THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

VOLUME XXVII.

FROM MAY 8, 1891, TO OCTOBER 30, 1891.

(RECAP)

LONDON:
Printed and Published for the Proprietors by GEORGE TUCKER, at the Offices of "THE ELECTRICIAN," Salisbury-court, Fleet-street, E.C.

1891.

Digitized by Google

INDEX TO "THE ELECTRICIAN."

VOL. XXVII.

General Alphabetical Index.

A

Abel, Sir Frederick, 179.
Accident at the Agricultural Hall, 431.
Accident on the Lichterfelde Electric Railway, 403.
Accumulator Cars at Birmingham, 429.
Accumulator Cars in Paris, 725.
Accumulator Traction, 2, 449.
Accumulators, Guaranteeing, 319, 349.
Accumulators, On the Chemistry of: by M. Cantor, 5 7.
ADAMS, A. J. S.
Contour of some Cosmical Variations and their apparent Teaching, 413.
Air Gap, On the Relation of the, and the Shape of the Pole Pieces to the Performance of Dynamo Electric Machinery: by Prof. Ryan, 638.
Alarm, Sensitive Electrical, 210.
Alloys during Fusion, Changes of Voltaic Energy of, 486
Alternate Current Curves, Dr. Frölich's Apparatus for, 707.
Alternate Current Curves, A Photographic Record of, 508, 603.
Alternate Current Motor System, A New, 508.
Alternate Current Motors: by E. Hospitalier, 392.
Alternate Current Theory: by Dr. W. E. Sumpner, 125.
Alternate Currents of very High Frequency and their Application to Methods of Artificial Illumination: by Nikola Tesla, 331.
Alternating Current Electric Supply Stations: by Dr. J. A. Fleming, 582, 607.
Alternating Current Electrolysis, 289.
Alternating Current, Electrolysis by means of: by Dr. Mengarini, 304, 324.
Alternating Current Flow in Circuits having Capacity and Self-Induction, On some Effects of: by Dr. J. A. Fleming, 17, 46, 74, 106.
Alternating Current Motors, Priority in, 544.
Alternating Currents differing in Phase, Transmission of Power by: by Von Dolivo-Dobrowolsky, 388.
Alternating Currents, Experiments with High Tension, 67.
Alternating Currents of High Frequency, Experiments with, 129.
Aluminium, 264.
Aluminium, Electrical Production of, 22.
Aluminium, Electricity in Production of: by Alex. S. Brown, 562.
Aluminium Smelting Dynamo, 282.
Aluminium Steam Boat, 351.
Alumino-titanium Alloy, 653.
Amateur Telegraphy, 4
American Census, Electric Lighting Statistics of, 516.
American Engineering Problem, 592.
American Institute of Electrical Engineers, 143, 647.

American Notes, 22, 53 84, 113, 143, 201, 228, 255, 282, 311, 340, 368, 397, 420, 450, 479, 564, 593, 647, 668, 697, 724.

ANDERSON, A.
Co-efficients of Induction, 10.
ANDRÉ, C.
A Contribution to the Study of Atmospheric Electricity, 260.
Andrews' Pendant Switch, 402.
Andrews' System of Concentric Wiring, 37.
Anglo-American Telegraph Company, 3.
Anglo-American Telegraph Company and the Paris-New York Telegraph Company, 21.
Annealing (Electric) of Steel Wire, 653.
Anti-Magnetic Alloys for Watches, 263.
Arc, A Photographic Study of the Electric: by Ed. L. Nichols, 139.
Arc Lamp Pole Device, 94.
Arc Lamps, Insulating Suspension for, 263.
Arc Lighting in Toronto, 571.
Arcas System of Electro Plating, 532.
Arco, 457.
Arcs, Application of Hydrocarbon to, 543.
ARMSTRONG, Prof. H. E.
A Discussion of the Chemical Changes occurring in the Planté Cell, 197.
ARONS, L.
On the Speed of Propagation of Electric Waves in Insulating Fluids, 157.
Asbestos in New South Wales, 151.
Asbestos, Production of, in the United States, 543.
ATKINSON, LLEWELYN B. and C. W.
Electric Mining Machinery, with Special Reference to the Application of Electricity to Coal-Cutting, Pumping, and Rock-Drilling, 557, 590, 644. *Discussion*, 646, 666, 695.
Atmospheric Electricity, 9, 351.
Atmospheric Electricity, A Contribution to the Study of: by C. André, 262, 269.
Auckland, Electric Lighting in, 486.
Austrian Navy, Electricity in the, 312.
Austrian Society of Electricians, 150.
Austrian Telephonic Statistics, 3.
Automatic and Multiplex Telegraphy, 208.
Avenue Trudaine Central Station, 144.
AYRTON, Prof. W. E.
On Alternate Current and Potential Difference Analogies in the Methods of Measuring Power, 199.
On the Magnetic Field in the Neighbourhood of the South London Electrical Railway, 521.
The Construction of Non-Inductive Resistances, 254.

B

Baden and Voslau, Projected Electric Railway between, 706.
Balata, Properties of, 292.
Bandsept Accumulator, 571.
Bankruptcy Courts, Electric Lighting of the New, 707.
Barking Road Cars, 2.
Barnet, 93, 179, 375.
Barnsley, 62, 63.
Bath, 3, 63.
BATTERIES (PRIMARY).
A New Dry Cell, 707.
Hellesen, 37.
Lalande Battery, 166.
BATTERIES (SECONDARY).
Lithanode Batteries, 691.
Tommasi Accumulator, 681.
Tudor and Correns Accumulators, 321, 592.
Wadde'l-Entz Accumulators, 84, 479, 647.
Bavaria, Electrical Utilisation of Water Power in, 458.
Bearing, A Novel Form of, 290.
Belgium, Electric Lighting in, 236.
BENNETT, A. R.
On the Telephoning of Great Cities, 475.
Berlin Electric Lighting Statistics, 209, 681.
Berlin Telegraph School, 120.
Berwick-on-Tweed, 3.
BIDWELL, SHELFORD.
Hellesen Dry Cell, 37.
Bills in Parliament, Electrical, 121, 150, 263.
Bimetallic Conductors, 152.
Binswanger-Coates Microphone, 502.
Birmingham Municipal Technical School, 515.
Birmingham Town Hall, Electric Lighting of, 653.
Bismuth in a Magnetic Field. On the Influence of Temperature and Molecular State on the Behaviour of: by P. Drude and W. Nernst, 141.
Bi-telephone, On a Small Telephonic Receiver known as the: by E. Mercadier, 251.
BJERKNESS, M. V.
Notes on the Decrement of Electrical Oscillations, 302.
Blakesley's Method of Measuring Power in Transformers: by Prof. Perry, 141.
Blondel's Method of Determining Alternate Curves, 598.
BLONDLOT, R.
On the Determination of the Dielectric Constant of Glass by the Aid of very Rapid Oscillations, 100.
Board of Trade Memorandum as to Photometers, 430.
Boilers, 32, 709.
Boilers, Cornish, 432.
Boilers Registration Bill, 32.
BOIS, H. E. J. G. DU.
Magnetic Circuits and their Measurements, 634.
Bombay, 5.
Boulengé Chronograph, 541.
Boulogne, 62.
Bournemouth Telephone Exchange, Fire at, 653.
BOUTY, E.
Dielectric Constant of Mica, 82.
Boy Messengers Company, 62, 319.
BOYS, C. V.,
Pocket Electrometers, 255.
Bradford, Electric Lighting at, 339, 544.
BRANLY, E.
Variations of Conductivity under Electrical Influence, 221, 448.
Bray, 624.
Brewers' Exhibition at the Agricultural Hall, 727.
Bridges Operated by Electric Power, 458.
Brighton, 264, 320, 458, 515, 542.
Brillié Meter, 179.
Bristol, 351, 431.
British Association, 209 290, 320, 429, 455, 458, 464, 555.
British Association at Cardiff, Sketch of Proceedings in Section A: by Dr. Oliver Lodge, 487.
British Association, Electrical Papers at, 468.
British Museum, Electric Light at, 179.
BROWN, A. S.
Electricity in the Production of Aluminium, 562.
Brown's (C. E. L.) 20 H.P. Three-Phase Alternate Current Motor, 657.
Brown Patent Rotary Engine, 637.
Brush Accumulator Patent, 397.
Brush Company's High-Pressure Switch, 410.
Brussels Communal Council, Report to the, 668.
Brussels Notes, 668.
Burton, 263.

C

Cable and Land Line Interruptions and Repairs, 121, 351, 458, 599, 707.
Cable, A New North Sea, 376.
Cable Competition, Atlantic, 208.
Cable Extensions, 2, 93, 179, 624.
Cable (New) between England and Germany, 405.
Cable (New) to Mauritius, 542.
Cable, Proposed Pacific, 180.
Cable Rates, Reduced, 237.
Cables, French Mediterranean, 357.
Cables, French West Indian, 377.
Cables in Conduits, a Thimble for Drawing, 637.
Cables, Japanese, 570, 707.
Cables, Lead covering for, 322.
Cables of the Société Française des Télégraphes Sous-Marins, 708.
Cables, Working Day of Submarine, 62.
CAHART, Prof. H. S.
Analysis of the Temperature Co-efficient of a Battery, 167.
Calcutta, Electric Lighting of a Bridge at, 570.
Callender Electric Pyrometer, 543.
Cambridge, Electric Lighting at, 207, 405.
Cambridge University, Engineering Department at, 351.
Canadian Electric Lighting Statistics, 570.
Capacity and Self-Induction of Overhead Telegraph Lines, 352.
Capacity Tests: by A. Dearlove, 268.
Capillary Electrometer, A Portable Form of: by A. Berget, 252.
CARDEW, Major P.
A Few Calculations on Electrical Shocks from Contact with High Pressure Conductors, 14.
Carlow, 209, 291, 325.
Cataphoric Medication, 151.
Caustic Soda and Chlorine Syndicate, 193.
Cavalry Telegraph, 571.
Celluloid, 629.
Central London Railway Bill, 93, 207, 350.
Central Station, Fire at an American, 450.
Central Stations, Electric Supply from, 130.
Chagford (Devon) 486.
Charging Station, Electric Launch Floating, 479.
Chelsea Electric Lighting Provisional Order, 180.
Chelsea Order, 319.
Chelsea Vestry, 290.
Chemical Changes Occurring in the Planté Cell: by Prof. H. E. Armstrong and G. H. Robertson, 197.
Chemistry of the Secondary Cell: by G. H. Robertson, 165, 178.
Chicago Auditorium, Electricity at, 32.
Chicago, Electric Lighting at, 293.
Chicago Exhibition and Chamber of Commerce, 654.
Chicago Exhibition, 264, 292, 321, 350, 378, 382, 412, 543, 571, 681, 708, 722.
Chicago Exhibition, Electrical Building at, 331.
Chimneys and Flues, 163.
Christiania, 2.
Christiania Central Station, 229.
Chronographs, Electromagnets for use with, 706.
Church Lighting, 457, 571.
Church Service by Telephone, 680.
City and Guilds of London Institute, 123, 654.
City and South London Railway, 93, 120, 377, 403, 707.
City and South London Railway, Electrical Disturbances caused by, 178.
City of London, Electric Lighting of, 119, 209, 241, 263, 457, 572.
City Notes, 29, 59, 89, 117, 147, 175, 205, 233, 259, 287, 317, 347, 374, 401, 428, 456, 482, 511, 540, 568, 596, 421, 649, 677, 703, 729.
Civil Engineers, Institution of, 93, 681.
Clark's Standard Cell, Memorandum on the Preparation of, 93, 98.
Clark's Standard Cells, Mr. Swinburne's Paper on the Causes of Variation in, 455, 500.
Clerkenwell Vestry, 263.
Clerk-Maxwell Scholarship, 2.
Clermont-Ferrand Electric Railway, Extension of, 485.
Clock for Showing Direction of Earth's Motion in the Ether: by Dr. Lodge, 200, 215.
Clocks by Alternating Currents, Driving Electric, 290.
Coal Mining (Electrical) in America, 682.
Coffin Welding Process, 2.
Cologne, 571.
Collieries, Electricity in, 263.
Combustible, A New, 185.
Commercial Cable Company, 93.
Commercial Efficiency and Brake Horse-Power, Mr. Stevenson on, 120.
Compagnie Continentale Edison, 312.
Compagnie Française des Telegraphes Sous-Marins, 150.

COMPANIES' MEETINGS, REPORTS, DIVIDENDS, STATUTORY RETURNS, &c—

(Abbreviations:—Mtg., Meetings of Shareholders; Rpt., Reports of Directors; Div., Dividend; Rev., Revenue; Stat., Statutory Returns.)

Akester Electric Motor Company—374; Stat., 427, 453.
Alcock Electric Light and Motive Power Company—Mtg., 232.
Aluminium Company—511.
American Bell Telephone Company—175.
Anglo-American Telegraph Company—Div., 348, 621; Rpt., 372; Mtg., 398.
Anglo-Portuguese Telephone Company—233; Rpt., 147; Mtg., 174.
Aurora Electric Lighting and Distribution Company—Stat., 703.
Automatic Electric Railway Signal Company—Mtg., 373.
Babcock and Wilcox—4; Mtg., 729.
Bath Electric Lighting and Engineering Company—Mtg., 511.
Bedford Electric Light Company—Mtg, 55.
Birmingham Electric Supply Company—116; Stat., 401.
Bournemouth and District Electric Light Supply Company—259, 453; Stat., 703.
Boy Messengers and Electric Call Company—59, 511.
Brazilian Submarine Telegraph Company—Mtg, 25, 702; Div., 147, 649; Rev., 29, 59, 89, 117, 147, 175, 205, 233, 259, 287, 317, 348, 421, 428, 454, 482, 512, 540, 568, 596, 621, 649, 677, 703; Rpt., 676.
British Electro-Chemical Agency—481.
British Insulated Wire Company—175.
Brockley Electric Lighting and Manufacturing Company—Stat., 373.
Brush Electrical Engineering Company—Rpt., 567; Mtg., 619.
Byng Telephone Company—453, 648.
Caledonian Telephone Company—205.
Callender's Bitumen Telegraph and Waterproof Company—Div., 621.
Caustic Soda Syndicate—Mtg, 204.
Cawthra (J.) and Company—Stat., 595.
Chelsea Electricity Supply Company—Mtg., 54.
Chili Telephone Company—Rpt., 286; Mtg, 316; Stat, 427.
China and Japan Telephone Company—Mtg., 175.
City of London Electric Lighting Company—317, 649; Mtg, 650.
City of London Electric Lighting (Pioneer) Company—596, 729; Stat., 373; Mtg., 116, 618, 649, 703.
City and South London Railway—Rev., 29, 59, 89, 117, 147, 175, 205, 233, 259, 287, 317, 348, 374, 401, 428, 512, 540, 568, 596, 622, 649, 677, 703, 729; Mtg., 203, 259, 423, 454, 482; Rpt., 400.
Collier Audible Telephone Syndicate—511; Stat., 595.
Commercial Cable Company—117; Div., 175, 540.
Compagnie Française du Telegraphe de Paris à New York—Mtg., 117.
Consolidated Telephone Construction and Maintenance Company—Div., 29, 729; Rpt., 89; Mtg, 115.
Council Bluffs (Iowa) U.S.A.—703.
Crompton and Co.—728; Rpt., 347; Mtg., 371, 728.
Cuba Submarine Telegraph Company—Rev., 29, 117, 259, 401, 512, 649; Div., 374; Rpt., 400; Mtg., 422.
Cuttriss, Wallis and Company—595.
Devon and Cornwall Electric Light and Power Company—427.
Direct Spanish Telegraph Company—Rev., 29, 147, 287, 401, 540, 649; Div., 512; Rpt., 567; Mtg., 617.
Direct United States Cable Company—343; Div. 677.
Eastern and South African Telegraph Company—317; Stat., 453.
Eastern Extension Telegraph Company—205, 317; Rev., 29, 147, 287, 402, 512, 649; Div, 259: Rpt., 676; Mtg., 700.
Eastern Telegraph Company—317, 593, 607; Rev., 29, 147, 287, 402, 512, 649; Div., 259, 287; Rpt., 315; Mtg., 315, 341.
"Eclipse" Electric Lighting Syndicate—649.
Edison and Swan United Electric Light Company—Rpt., 317; Mtg., 287, 345; Stat., 453.
Electric and General Investment Company—147; Rpt., 175; Mtg., 203; Stat., 373; Div., 729.
Electric Arms and Ammunition Syndicate—703; Mtg., 672; Stat., 729.
Electric Construction Corporation, 649.
Electric Installation and Maintenance Company—454, 677.
Electric Traction Company—512, 729.
Electric Welding Company—649, 677, 729.
Electrical Engineering Corporation—453.
Electrical Supplies and Fittings Company, 677.
Energy, Gas, Electric Light and Power Company—481.
European Sims-Edison Electrical Torpedo Company, 649.
Exchange Telegraph Company—Stat, 453.
Freedman Battery Company, 677.
Froude-Hurtell Torpedo Company—Stat., 595.
General Zinc Recovery and Lighting Company—Mtg, 453.
Globe Telegraph and Trust Company—Div., 317; Mtg., 368.
Great Northern Telegraph Company of Copenhagen—Mtg., 26; Rev., 29, 147, 288, 402, 540, 650.
Greenwood and Batley, 59.
Halifax and Bermudas Cable Company, 259, 622.
Head, Wrightson and Company—Stat., 427.
Henley's Telegraph Works Company—Stat., 649; Mtg., 677.
Herold Telegraph Company of Berlin—374.
Hornsby (Richard) and Sons—Div., 89.
House-to-House Electric Light Supply Company—Rep., 205; Mtg., 232, 427; Stat, 373.
India Rubber Estates Company, 117.
India Rubber, Gutta Percha, and Telegraph Works Company, 285.

COMPANIES' MEETINGS, &c. (continued)—

Indo-European Telegraph Company—Mtg., 116; Div., 730.
Institute of Medical Electricity—677.
International Electric Syndicate—511.
International Okonite Company—Mtg., 540, 674.
Ipswich Electricity Supply Company—453.
Johannesburg Gas Company—Mtg., 316, 427, 730.
Kensington and Knightsbridge Electric Lighting Company—Mtg., 27.
Laing, Wharton and Down Construction Syndicate—649.
Lancashire and Yorkshire Electric Lighting Company—Stat., 427.
Laws' Electrical Appliances Company—729.
Liverpool and District Pulsion Telephone Company—Stat., 649.
Liverpool Overhead Railway—Mtg., 426.
London Platino Brazilian Telegraph Company—482.
Maclellan and Company—Div., 402.
Maitland and Company—Stat., 649.
Manchester Edison-Swan Company Mtg., 372; Stat, 427.
Manganese Brass and Bronze Company—Div., 348; Mtg., 428.
Manitoba Electric and Gas Light Company—233.
Maxim-Weston Electric Company—703.
Metropolitan Electric Supply Company—Stat., 401.
Middlesborough (Kentucky) Electric Light Company—Mtg., 678.
Montevidean and Brazilian Telegraph Company—288; Mtg, 423.
Monte Video Telephone Company—Rpt., 728.
Municipal Electric Light and Power Corporation—481.
National Electric Supply Company—677, 704.
National Telephone Company—175, 317, 650; Rpt., 259; Mtg., 284.
New Shanghai Electric Company—Mtg., 286.
New Telephone Company—427.
North Metropolitan Tramways Company—374.
Norwich Electricity Company—Stat., 729.
Notting Hill Electric Light Company—117, 175; Mtg., 146.
Oriental Telephone Company—Mtg., 27.
Panulcillo Copper Company—Mtg., 89.
Queen Anne's Mansions Lighting and Heating Company—259.
Ruston, Proctor, and Co., 59—Div., 89; Mtg., 117.
St. James's and Pall-Mall Electric Light Company—59, 288, 678; Div., 259.
Sanitas Company—374.
Series Electric Traction Syndicate—317.
Shropshire Electric Light and Power Company—453; Stat., 373.
Siemens Bros. and Company—Stat., 453.
Société Anonymé des Mines et Fonde ie de Zinc de la Vielle Montagne—Rpt., 89.
Société Générale des Telephones—233.
Spanish National Submarine Telegraph Company—117; Div., 348.
Stamford Hill, Tottenham and Edmonton Electric Light and Power Supply Company—373.
Stewart and Clydesdales—Div., 402.
Submarine Cables Trust—622; Mtg., 28.
Telegraph Construction and Maintenance Company—Mtg., 288, 317.
Telephone Company of Austria—233; Rpt., 347; Mtg., 368; Stat., 453.
Telephone Company of Ireland—Rpt., 370; Mtg., 370.
Union Electrical Power and Light Company—481.
United River Plate Telephone Company—Rpt., 373; Mtg, 423.
Venezuela Telephone and Electrical Appliances Company 347.
West African Telegraph Company—288; Rpt., 233; Mtg., 257.
West Coast of America Telegraph Company—233; Rpt., 25; Mtg., 87; Rev., 259, 540, 650; Stat., 401.
West India and Panama Telegraph Company Rpt., 28; Mtg., 56; Rev., 29, 89, 147, 259, 288, 348, 402, 512, 540, 596, 650, 730.
Western and Brazilian Telegraph Company—Rpt., 28; Mtg. 57; Rev., 29, 59, 89, 117, 147, 175, 205, 233, 259, 288, 318, 374, 402, 402, 482, 512, 540, 568, 596, 622, 650, 678, 704, 730; Div., 730.
Western Counties and South Wales Telephone Company—Rpt., 28; Mtg., 88; Div., 428.
Westminster Electric Supply Corporation—730.
Weybridge Electric Supply Company—Stat., 596.
Williamson's Electrical and Engineering Company—428; Mtg., 401.
Winfields—Mtg., 650.
Woodfield Syndicate—89.
Woodhouse and Rawson—428.

COMPANIES (NEW) REGISTERED—

Abercarne Engineering and Foundry Company, 648.
Agencé Dalziel, 233.
Albert Electric Lighting Company, 175.
Albion Clay Company, 89.
Anders, Elliot, and Chetham-Strode, 453.
Andover Gas and Coke Company, 205.
Anglo-American Construction Company, 567.
Arc Accumulator Company, 117.
Armstrong's Glass Company, 29.
Art Workshops, 89.
Atlas Carbon Manufacturing Company, 621.
Aurora Electric Lighting and Distribution Company, 175.
Babcock and Wilcox, 259.
Bath Electric Lighting and Engineering Company, City of, 59.
Berk and Co., F. W., 453.
Bibby Steamship Company, 175.
Boy Messengers and Electric Call Company, 59.
Bournemouth and District Electric Supply Company, 175.

COMPANIES (NEW) REGISTERED (continued)—

British Electric Installation Contractors, 677.
British Electrolytic Syndicate, 29.
British Electro Chemical Agency, 453.
British Mexican Estate Company, 703.
Brown's Engine Company, 595.
Caledonian Telephone Company, 511.
City of London Electric Lighting Company, 3.7.
Clegg's Metal Incandescent Lamp Co., of France, 117.
Combination Tyre Company, 481.
Commercial Contract Corporation, 175.
Crossley, Geo., 89.
Cullingworth Gas Company, 539.
Darlaston Cycle Company, 481.
Dobson and Barlow, 539.
East London Electric Supply Company, 287.
Economic Brick Co., 729.
Electrical Advertising Syndicate, 29.
Electrical Assets Purchase Company, 401.
Electric Welding Company, 481.
Elektrizitat-Gesellschaff in Hamburg, 453.
Electrolytic Caustic Soda and Chlorine Trust, 233.
Endurance Seamless Tube and Vial Company, 427.
"Energy" Gas, Electric Lighting and Power Co., 401.
"Engineering," 427.
Epstein Electric Accumulator Company, 401.
Estates Improvement Company, 481.
Etchells Brothers, 287.
European Sims-Edison Electrical Torpedo Co., 59.
Evans and Co, Joseph, 347.
Fair Mount Syndicate, 287.
Fibrate Syndicate. 539.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 677.—Vol. XXVII. FRIDAY, MAY 8, 1891. Price Fourpence.

NOTES.

Electrical science was well represented at the conversazione of the Royal Society on Wednesday evening, both as regards the guests and the exhibits. Mr. Wimshurst showed his very interesting alternating influence machine. Our readers need not be alarmed at the immediate development of a new and complicated branch of electrical science, such as that which has grown round the alternating dynamo. The machine, which has many points of theoretical interest, performs one experiment. It will not charge a Leyden jar. Mr. Gordon had erected the Tomlinson sub-station regulator which was recently shown at the Institution of Civil Engineers. It looks like a cross between a guillotine and a railway signal-box, and is intended to control transformers of an output of 1,000 H.P. Mr. Gordon has published some very striking figures as to the economy of the system, but these must be studied with care before any opinion can be formed as to the value of the very ingenious mechanism.

Dr. Oliver Lodge exhibited a high-speed revolving mirror for analysing sparks, and two clocks for continually pointing out the direction of the earth's orbital motion, so that at any moment it can be seen in which direction we are rushing through the ether. He also showed two gallon Leyden jars, with independent circuits, one having an adjustable self-induction, consisting of two straight wires with a sliding cross-piece. The circuits could thus be tuned to resonance, and on the discharge of one the other resounds and overflows. Mr. Shelford Bidwell showed his interesting adaptations of selenium cells, Prof. Crookes his phosphorescing gems; and some forms of Clark cells, provided with valves and stirrers, were exhibited by Prof. Schuster.

In another column we describe two new methods of measuring self-induction, reproduced from an article by Prof. Anderson, in the *Philosophical Magazine*. The methods show a great deal of ingenuity, and the later one seems to possess considerable merit from a practical point of view. The first method does not appear as if it would prove useful. A complicated key is required, and the formula can only be applied when the resistance of the galvanometer is known. As galvanometer coils are wound with copper wire, whose temperature is always uncertain, this defect is a serious one. A further disadvantage is caused by the fact that the formula involves the product of the sines of two angular deflections, and this is not readily obtained from the readings of the instrument, although the ratio of the two could be found with ease. The other method is much simpler, and consists of a modification of one of Maxwell's condenser methods. It can be applied to any Wheatstone bridge, and has the additional advantage of being a null method. We think the merits of null methods are frequently over-estimated. It is no doubt true that with such methods a very sensitive instrument can be used, and all error due to uncertainty of the calibration of the galvanometer is eliminated; but in practice these advantages are valueless, because the sensitive instrument is not generally at disposal, and the connection between the deflection and the current is known quite as accurately as is necessary when the other sources of experimental error are considered. Null methods are always slower and more troublesome than deflectional methods, and, as a rule, it is quicker and more accurate to take the mean of several observations by the latter, than one observation by the former. The difference between them is something like that distinguishing a Siemens dynamometer from a direct reading deflectional instrument. Although for some purposes the former must be used, the advantages it possesses are, as a rule, more than counterbalanced by the quickness and convenience of the latter.

In *The Electrician* for April 24 we alluded to a method, suggested by M. Boucherot, for obtaining a constant current supply of electrical power from a pair of mains kept at constant potential. The device consisted a new kind of transformer formed by combining an inductive coil with a condenser, and, in two further numbers of our contemporary, *L'Electricien*, M. Boucherot enters with great elaboration into the various modifications which can be made in this new type of converter. He shows that the constant current circuit need not necessarily be non-inductive, and may consist of the primary coil of a transformer; and he pictures an installation in which a constant potential dynamo supplies a pair of mains which are tapped at places by transformers of the ordinary type for constant potential circuits, and at others by transformers of the new type for constant-current distribution. He also claims to have been so far successful with a particular converter, supplied with a constant potential of 800 volts, as to obtain from it a constant current of one-third of an ampere at potentials varying between 100 and 1,000 volts. While he may be congratulated on this success, his bare statement that the new transformers will only cost as much as those of the ordinary type for the same output at once challenges contradiction.

Digitized by Google

Condensers of from 100 microfarads cannot be obtained at such a moderate price as M. BOUCHEROT appears to think, nor are there any condensers yet in the market which can be guaranteed to stand the potentials to which they would have to be subjected in practice.

THE examination question, alluded to by a correspondent, in which an explanation is asked of the terms series-multiple, multiple-series, series-parallel, and parallel-series, is a monstrous one. Our correspondent is quite justified in thinking that they are vague. He asks, "Could not the word arc be entirely abolished, and for multiple substitute parallel?" and adds, "Why do not electricians confine themselves simply to the terms series and parallel?" To this we reply that these senseless terms have long ago been abolished, and electricians *do* confine themselves simply to the terms series and parallel. We are surprised to learn that such expressions still linger in the lecture rooms.

WE beg to decline to adjudicate on the application of these ill-devised terms to the illustrations from Mr. URQUHART'S book. Engineers would describe the first arrangement as consisting of various groups of lamps in series (or series groups of lamps), on 200-volt mains, and the second as various parallel groups of lamps on a series circuit. These systems are so rarely used that the ingenuity of the word-coiner is not required. We should like to see four or five-candle lamps more generally used for domestic lighting. It is impossible to make a practical 100-volt four-candle lamp, and it would be, therefore, necessary to wire them in series; but it would assuredly be unnecessary to give this method of wiring any of the clumsy names alluded to by our correspondent.

Finsbury Technical College.—The students of this College will hold a conversazione on Friday evening next, at 7.30 p.m.

Electric Traction at Florence. — The Florence-Fiesole line has been reopened, the cars being fitted with a new style of electric brake.

Lyons.—According to the *Bulletin International de l'Electricité*, the First of May "manifestants" managed to cut some 600 underground telephone wires.

Electric Alarms in Mexico.—Some 20 electric fire alarms are to be set up in the City of Mexico. These are of various makes, and the best will be ultimately selected.

The St. James and Pall Mall Company.—The current sold by this Company for the quarter ending March 31, 1891, brought in £9,652, as against £1,818 for the corresponding period last year.

Accumulator Traction.—According to the *Elektrotechnischer Anzeiger* experiments in traction have been carried on for some time by Messrs. Siemens and Halske on the Lichterfelde-Teltow line, Tudor accumulators being used.

Crystal Palace Electrical Exhibition.—This Exhibition will be opened in November next, and will be continued for some months. No charge will be made for space. For further particulars see our advertisement columns.

The Barking-road Cars.—It is stated that the contract for the accumulator cars on the Barking-road line has been renewed with the General Electric Power and Traction Company at an extra penny per car mile—that is, at 5½d. per car mile.

The Government and the Telephones in Italy.—The proposed law for the acquisition of the Italian telephone system will shortly be laid before Parliament, and it is to be hoped that it will pass both Chambers before the end of June.

Standards of Illumination.—The figure accepted abroad as the ratio between a Hefner-Alteneck amylacetate standard lamp and the English standard candle is, that one Hefner-Alteneck lamp = 8·186 English candle.

Personal.—Mr. Percy E. Scrutton informs us that he is no longer connected with the Electrical Engineering Corporation, and has accepted the post of manager of a London branch recently opened by Mr. L. C. Howell, of Llanelly, at 24, Queen Victoria-street, E.C

Clerk-Maxwell Scholarship.—The Clerk-Maxwell scholarship for the advancement by original research at the Cavendish laboratory of experimental physics, especially of electricity, magnetism, and heat, has been awarded to William Cassie, M.A., of Trinity College.

Christiania.—Some £25,000 have been voted for building a central lighting station at Christiania according to the plans of Herr Knud Bryn. Tenders will be shortly invited for executing the work, which will be carried out on the three-wire system, and will be capable of supplying 4,000 16 c.p. lamps.

Copper.—Messrs. Merton's annual statistics of the copper production of the world show that the output of 1890 reaches the highest figures yet attained. The production of the United States has more than doubled since 1883, and last year's outturn was upwards of five times that of 1879.

The Junior Engineering Society.—On Saturday afternoon last a large party of members of this Society visited the Tower Bridge Works. They were received and shown over by Mr. E. W. Cruttwell, the resident engineer, who afforded every facility for a complete inspection of the bridge so far as it has advanced, and explained its construction and erection.

The Anglo-American Telegraph Company.—This Company notifies having opened a cable office in Montreal, which is in direct communication by special wires with their cable station in Newfoundland, thus giving the cabling public every facility for speedy transmission of messages. The entire route from Glasgow to Montreal is under their independent control.

Cable Extensions.—We understand that negotiations are proceeding between the Imperial Government and the Eastern and South African Telegraph Company for laying a cable from Zanzibar to Mauritius, *viâ* the Seychelles. The French Government are also considering the question of connecting the Island of Réunion with Mauritius in the event of the cable being extended to the latter place.

Electrical Standards Committee.—A meeting of the Electrical Standards Committee was held on Monday at the Board of Trade. The following members were present:—Sir W. Thomson, Lord Rayleigh, Prof. Carey Foster, Mr. Glazebrook, Dr. John Hopkinson, Mr. Preece, Mr. Graves, Major Cardew, and Mr. Courtenay Boyle. Prof. Silvanus Thompson attended, and gave evidence on behalf of the London County Council.

Munich.—Herr O. Von Miller has laid before the Munich Town Council a project for the electric lighting of the town. It is proposed to derive 2,200 H.P. for the purpose from turbines driven by water from the Isar. The number of lamps is to be 9,500, and the capital required is estimated at £155,000. The annual cost of running is put at £30,000, and a surplus of £10,000 is worked out. At this rate electricity will cost only two-fifths the price of gas.

The Coffin Welding Process.—Experiments are being made with this continuous current welding process, which is being put forward as an improvement on the alternating current method. We are informed that a 1 inch bar can be welded with the current direct from a dynamo with a 1 h.p. engine. It is claimed that this process can utilise the current supplied from central stations, and, dispensing, as it does, with transformers, will enable electrical welding to be adopted by a large number of metal workers.

The Decimal Association.—A joint deputation from the Associated Chambers of Commerce and the Decimal Association will be received to-day by Mr. Goschen and Sir Michael Hicks-Beach to urge the Government to take the necessary steps for rendering compulsory the adoption of the metric system of weights and measures, as the first stage in the introduction of a complete decimal system. The Decimal Associa-

Digitized by Google

tion will present a petition praying for the appointment of a Royal Commission or Select Committee.

Berwick-upon-Tweed.—The Lighting Committee of the Urban Sanitary Authority have reported that they have fully gone into the matter of lighting the town. Finding that the gas company were not disposed to meet them either in price or quality of the gas, they directed their attention to the electric light. The result is that one firm of electrical engineers has offered to undertake to erect, work, and maintain an electric light installation for a period of five years, the proposed installation to consist of 21 arc lamps of 2,000 c.p. nominal, and 20 20 c.p. incandescent lamps.

The Telephone and the Telegraph in Paris.—In November last the French Postal Telegraph Department inaugurated experimentally a service of "telephonic messages." This new service allowed the public to telephone a telegram from any telegraph office provided with telephonic apparatus to any of the ten chief telegraph offices in Paris. This service has been so much appreciated that the area served by it is to be extended and the system definitely adopted. Moreover, exchange subscribers are to be allowed to send "telephonic telegrams" from their own houses, at the rate of 50 centimes per five minutes' conversation.

Electrical Patents.—Referring to the proposed celebration on the 25th of this month of the centenary of the French Patent Office system, *La Lumière Electrique* remarks on the extreme rarity of electrical patents previous to and for long after 1791. In France, in 1809, a patent was taken out for lighting ships' compasses, and in 1819 a doctor patented an electrical machine. In England a patent was taken out in 1766 for a marine compass. In 1782 an electrical machine for giving positive and negative electricity, and in 1792 a magnetic ore separator were patented. In America no electrical patents were heard of until the beginning of the present century.

Royal Institution.—The annual meeting of the Royal Institution was held on Friday last. The real and funded property of this Institution now amounts to above £83,000, entirely derived from the contributions and donations of the members. Fifty-six new members were elected in 1890, and 63 lectures and 19 evening discourses were delivered. The books and pamphlets presented amounted to about 285 volumes, making, with 561 volumes (including periodicals bound) purchased by the managers, a total of 846 volumes added to the library in the year. The following gentlemen were unanimously elected as officers for the ensuing year:—President, the Duke of Northumberland; treasurer, Sir James Crichton Browne; secretary, Sir Frederick Bramwell.

Bath.—At the fortnightly meeting of the Surveying Committee, held on Monday, the report of the Electric Lighting Committee on Prof. Forbes' report was considered. The Committee asked the Authority to retain a competent electrical engineer to make periodical visits in order to test the conditions of the circuits, to examine the street lighting, and to note the constancy of the electric pressure of the incandescent lamps; and to authorise them to supply a few additional arc lamps to those parts where the lights are now too far apart. The Electric Committee believed that not more than 12 lamps would be required to greatly improve the street lighting. Mr. Massingham was present, and in answer to questions stated that the frosted globes took off from the light 30 or 40 per cent., but they distributed the light better. The report was adopted.

The Endowment of Research.—At the last meeting of the Académie des Sciences it was announced that the late M. Cahours had left the Académie the sum of 100,000fr., the annual interest from which was to be devoted to aid necessitous science students in completing any valuable scientific research they might be engaged in, chemical research to be especially considered, the premiums to cease as soon as the holders of them have obtained well-remunerated posts. M. Janssen, alluding to M. Cahours' bequest, remarked that the gift was not only important in amount, but as marking a new departure in the form of awards at the disposal of the Académie. The usual prizes of the Académie were beyond the reach of beginners, and yet amongst these how much talent was there not, which, properly cultivated, would prove a gain and an honour to science.

Austrian Telephonic Statistics.—At the end of 1889 the State possessed telephonic exchanges in 28 towns, to which the total number of subscribers was 664, or less than 24 per exchange. The figures for the exchanges erected by private enterprise are as follows:—

Town.	Population.	Subscribers.	Subscribers per 1,000.
Vienna	1,200,000	1,614	1·34
Prague	294,000	640	2·17
Trieste	133,000	483	3·63
Lemberg	110,000	330	3·00
Graz	100,000	341	3·41
Brünn	82,600	374	4·52
Linz-Urfahr	50,000	186	3·72
Czemswitz	45,000	111	2·47
Pilsen	45,000	134	2·97
Reichenberg	35,000	318	9·08
Bielitz-Biala	30,000	145	4.38

Physical Society.—As we recently announced, a special meeting of this Society will be held at Cambridge to-morrow, May 9th. The programme of proceedings is as follows:—Leave Liverpool-street at 11 o'clock in train with special saloon carriages (first and third class). On arrival at Cambridge at 12:17 the members of the Physical Society will become the guests of the Cambridge members. Lunch in the hall of Emmanuel College, by permission of the Master and Fellows, at one o'clock. Meeting at the Cavendish Laboratory at 2:30, when Papers will be read by Prof. J. J. Thomson and Messrs. W. C. D. Whetham, S. Skinner, W. N. Shaw, and R. T. Glazebrook. Members will afterwards have an opportunity of seeing the Cavendish Laboratory and other University laboratories. At six o'clock there will be tea in Trinity College Combination Room, by permission of the Master and Fellows. Particulars of the Papers to be read will be found in our Societies' Meetings column.

Liverpool Corporation Laboratory.—At the meeting of the Lighting Committee of the Liverpool Corporation, on Monday last, the City Engineer presented a report by the Electric Inspector to the effect that the alterations and enlargements to the test room and office had been completed, and the apparatus formerly in the hands of the Liverpool Electric Supply Company, Limited, had been taken over at a total cost of £392 10s. 6d., and Mr. Yeaman reported that specifications of the instruments required to complete the equipment of the laboratory had been sent to eight first class firms, and a vidimus of offers was submitted. After some discussion the tender of Messrs. Nalder Brothers and Co, for certain instruments, amounting to £264 17s., was accepted, and it was decided to obtain special instruments from White, of Glasgow, and Siemens, of London, at a cost of £88 and £43 8s. respectively. The appointment of a junior assistant in the laboratory was postponed for a fortnight.

Frankfort Exhibition.—The Allgemeine Elektricitäts-Gesellschaft and the Maschinenfabrik Oerlikon have now definitely undertaken to contract for transmitting power electrically from Lauffen to Frankfort, and are bound under heavy penalties to finish the work at the latest by August 15th. There is, therefore, no longer any doubt but that this important experiment, the successful issue of which will greatly interest the scientific world, will soon be an actual fact.—We have received the first three numbers of *Elektrizität*, the official journal of the Exhibition. This journal is profusely illustrated, and contains a large amount of useful information on subjects connected with electricity in general and its display at the Frankfort Exhibition.—The Committee of the Exhibition have decided to reserve a special building, to be opened on June 15th, for a collection of plans, projects, and results of central station working, which they think will be useful, not only in connection with the Municipal Congress but to the general visitor.

Electric Traction on the South Staffordshire Lines.—At the meeting of the Wednesbury Town Council, on Monday last, the Town Clerk reported that he had received an application from the South Staffordshire Tramway Company for the sanction of the Council to the introduction of electricity as a substitute for the steam, upon the Wednesbury and Walsall tram lines. Alderman Williams said objections had also been made to the

Digitized by Google

poles proposed to be used, but from what he had seen they were not unsightly but ornamental, and the probability was that some day they would be utilised for public lighting. Alderman Wilson Lloyd, in seconding the resolution, said he was convinced that, by substituting electric traction for steam engines, something would be done for the comfort of the town and of the people. Eventually it was unanimously decided that the application should be granted subject to a proper agreement being entered into with the Town Council, the conditions to be inserted in the agreement to be approved by the General Purposes Committee.

Glasgow.—The special sub-committee of the Town Council on electric lighting, having considered the reports of Mr. Crompton, Sir William Thomson, and Professor Jamieson, have made the following recommendations:—(1) That the Town Council should themselves undertake the laying down of the necessary plant. (2) That the system of supply should, as far as may be found expedient, be in accordance with the reports obtained. (3) That, if the recommendations now made are approved, the matter be remitted back to the sub-committee to arrange for acquiring a suitable site for the erection of a central station, and to take all other necessary steps for carrying out the proposed works. The cost of putting down the plant requisite for supplying 11,000 16 c.p. lamps (exclusive of cost of sites for central station and sub-station) is estimated at £51,307. The sub-committee also suggest that they might be authorised to consider and report whether any, and, if so, what, arrangement could be made with Messrs. Mavor and Coulson with regard to the purchase of their undertaking. The report was considered by the Town Council yesterday, and the matter adjourned for a month.

The Davenport Patent.—In the *Electrical World* of April 25th are printed four letters written by Thomas Davenport, the American inventor of the electric-motor, to the Hon. Elijah Paine, a Justice of the New York Supreme Court and Davenport's financial supporter. The letter dated January 26, 1847, contains the following passage: "I have the opinions of many, with my own, that the use of electro-magnets to propel Prof. Morse's telegraphic apparatus is an infringement on my patent. William P. Elliot, patent agent at Washington, is of the same opinion. You are aware, probably, that my patent gives me the '*application of magnetic and electro-magnetic power as a moving principle for machinery.*' . . . It seems to me, on comparing my invention to that of Prof. Morse, that the telegraphic companies, after running their wires a '*considerable distance*,' and ascertaining that they can magnetise iron at such a distance, should stop, and contract with me and my associates for the right of using electro-magnetic power to propel their telegraphic machinery." Our New York contemporary is of the opinion that the Davenport patent is the most remarkable example of the admission of a sweeping claim to be found in the history of the Patent Office, not even excepting the Bell telephone patent.

The Action of Oils on Metals.—The *American Journal of Railway Appliances* gives some particulars of a series of tests on the action of various oils on the different metals in contact with them. The experiments lasted some twelve months, and the *modus operandi* was as follows: The metals were first thoroughly cleaned in ether and then dried. They were next carefully weighed and placed in closed vessels filled with oil, which were kept for one year at a uniform temperature in summer of 80°F., and in winter of about 50°F. The following were the results obtained:—In the case of iron, seal oil acted the least on it and tallow the most. Bronze was not attacked at all by colza oil and but very slightly by olive oil; it was, on the other hand, vigorously eroded by linseed oil. In the case of lead, the most deleterious lubricant was whale oil, and the best lubricant was olive oil. Whale, lard, and sperm oils were about equally erosive. Zinc seemed to be but little attacked by mineral lubricating oils, the best oil was lard and the worst sperm. Copper was not attacked by any of the mineral oils, sperm oil had the least and tallow the most action on it. Generally speaking, mineral oil attacked the metals under test the least, and sperm oil attacked them the most. For the lubrication of the bearings of heavy machines, a mixture of colza or sperm oil with a mineral oil is recommended, for they have but little action on bronze or cast iron. Tallow having considerable erosive action on iron, its use should be avoided as much as possible.

Electricity on the Stage.—At a New York theatre an attempt was made to impart a little more realism to the usual theatrical horse-race by causing the scenery to move rapidly across the stage. On this occasion the necessary power was obtained from electric motors, owing to the great ease and promptness with which their speed could be varied to suit the exigencies of the race. More recently, at the Théâtre des Variétés at Paris, this device has been considerably improved upon. At the Théâtre des Variétés not only does the scenery change, but the horses, instead of stand-stationary, as at the New York theatre, are trained to actually gallop, while the track underneath them revolves rapidly in the reverse direction. The three tracks are placed parallel to one another, and each consists of a thick carpet fixed on to an endless belt revolving round drums of 5½ft. in diameter by 3ft. broad, arranged 9 yards apart, the belt being supported between the drums by small rollers placed at intervals of 8in. Each belt is driven by a motor through tooth gearing. The speed of the motors is regulated by rheostats, and some skill is necessary in their manipulation, since, while it is necessary to attain the full belt speed of 2,640ft. per minute (30 miles an hour) in under 10 seconds, there must be no abrupt changes. The race lasts 1½ minutes. The motors are supplied with current from accumulators in the Popp sub-station in the Rue Feydau, and with the pressure at 100 volts they require about 100 amperes (13¼ H.P.) on starting, and about 25 amperes (3¼ H.P.) when in full swing.

Amateur Telegraphy.—At Richmond (Ind.), a city containing about 20,000 inhabitants, there exists, says the *Electrical World* of New York, a telegraph organisation known as the Richmond Local Telegraph Company. The organisation is composed of amateur telegraphers, and its object is to secure a means of frequent communication and social enjoyment for its members. Its officers receive no compensation for their services, and the fees charged cover only the actual expenses involved. This private telegraph line has now been in operation some five years, and has proved a fruitful source of amusement and recreation as well as instruction to the members of the Company, several of whom are now occupying good positions secured through the practical knowledge gained in the operation of the private line. The total length of the line is between four and five miles, and extends from one end of the town to the other, in a somewhat irregular course. The members of this small Company have endeavoured to make the line more substantial and permanent in its character than the average private line, and are very proud of the result. Each subscriber is expected to keep his own instruments in proper order, but beyond that is not concerned with the care of the line. The battery, line wire, and materials are the property of the Company, the office connections and instruments belonging to the individual members. An admission fee of $2 is charged to cover the cost of necessary additional battery, and a regular monthly fee of 25 cents is assessed to meet the expense of maintaining the line and battery.

The Naval Exhibition.—The general lighting of this exhibition, which was opened on Saturday last, is carried out by Messrs. Siemens Bros. and Co. The generating plant consists of seven multitubular Davey-Paxman locomotive boilers, working at 120 lbs. pressure; six Willans engines, and three continuous current Siemens' machines, having an output of 1,500 amperes at 120 volts, coupled direct and running at 350 revolutions per minute. This firm also supply two smaller dynamos, having an aggregate output of 72 kilowatts, and a Siemens alternator, furnishing 500 amperes at 80 volts for the powerful search light at the summit of the model Eddystone lighthouse. The mains are of the Siemens lead covered and iron armoured type, and the lighting is chiefly carried out by means of new pattern 9 ampere Siemens arcs, working two in series. Some 10 miles of conductors have been laid, and 200 arc, and about 5,000 incandescent lamps, installed within nine weeks of the signing of the contract. The whole of the telephonic communications connecting the various executive offices and the fire and police stations have been erected by the Universal

Digitized by Google

Telephone Company. Amongst the exhibitors are Messrs. Latimer Clark, Muirhead, and Co., who supply the current for lighting the whole of the incandescent lamps in the Camperdown Gallery, and Messrs. Ronald Scott, who show switch boards, and a 11 unit dynamo for the search light over the grand stand. The General Electric Power and Traction Company, Messrs. Greenwood and Batley, Messrs. Clarke, Chapman, and Co., and the Planet Electrical Engineering Company, also exhibit. The exhibition is in a very complete state, and forms a refreshing contrast to the dreary succession of vacant spaces of the average exhibition at the time of opening.

Leeds.—The terms of the Order to be granted to the Yorkshire House-to-House Company have been agreed to by the parties concerned, viz., the Board of Trade, the Leeds Corporation, and the Company. As the Order contains some peculiar clauses, the following brief abstract may be of interest. The maximum price is fixed at 8d. per unit, but the following discounts are to be allowed:—

For 200 hours' consumption—		
	during any quarter	5 per cent.
300	,,	10 ,,
400	,,	15 ,,
500	,,	20 ,,
600	,,	25 ,,
700	,,	27½ ,,
800	,,	30 ,,
900	,,	33½ ,,
1,000	,,	35 ,,

These discounts work out: For 500 hours' use per quarter, under 6½d. per unit; for 1,000 hours, 5 1-5d. per unit. A sliding scale for sharing profits was also demanded by the Corporation, but the Board of Trade objected. As to the terms of purchase by the Corporation, there are no less than three alternative schemes. By Act of Parliament the Company has a right to exist for 42 years. But the Company has agreed to forfeit its rights at the end of 31 years—if required by the Corporation to do so; no goodwill or compulsory purchase is to be allowed for; and only such works as are suitable for carrying on the undertaking are to be valued. Another scheme gives the Corporation the right, after the expiration of 21 years, to purchase the plant at its then value, and to pay, in addition, such sum for goodwill as the arbitrator may determine. Another alternative is that the Corporation may, *at any time*, require the Company to sell the undertaking for such an amount of Leeds Corporation Stock as will produce, by the interest thereon, an annuity of 5 per cent. per annum upon the sum properly expended by the Company and chargeable to capital account. If, however, purchased before the expiration of 10 years, then the Corporation must pay in addition a sum equal to the aggregate amount of a dividend of 5 per cent. per annum on the capital expenditure, less the aggregate amount of the dividends previously declared by the Company.

Bombay.—The proposal for the experimental introduction of electric lighting in a certain area of the City of Bombay has, says the *Indian Engineer*, been modified at the instance of the Municipal Commissioner. Messrs. Volkart Brothers, who are the representatives in India of Messrs. Ganz & Co., of Buda Pesth, are to be invited to send in proposals for the lighting of the road from the Crawford Markets to the Victoria Station, and thence to the Frere Fountain, or so much of that area as the money in hand—rather less than Rs. 60,000—may justify. The original advertisements inviting tenders in England and the United States brought only three tenders. This lack of enterprise was, no doubt, mainly due to the conditions laid down, by which competitors were to bind themselves to provide all the plant necessary, and make the experiment at their own risk for a period of two years certain. At the expiration of the two years there was nothing to bind the Corporation to go on with the experiment, whether successful or not, or to purchase the plant. Some of the largest firms declined to even consider the proposal, on the ground that the risk and the cost would not be counterbalanced by any fair prospect of equivalent return. Under these circumstances, the Municipal Commissioner came to the conclusion that it was useless to ask firms to lay down expensive plant with no security that it would be purchased or the contract renewed after the lapse of two years. He proposed two alternatives—that the Municipality should purchase its own plant at a cost of two and a-half lakhs, or that they should contract with Messrs. Ganz, or some other well-known firm, to light a small area experimentally for a year or two. The second alternative has been approved by the Standing Committee.

The Sims-Edison Torpedo.—The facility and precision with which energy can be applied at a distance by electricity was beautifully illustrated, says *Engineering*, at a private trial which lately took place of the Sims-Edison electrical torpedo at the yard of the Forges et Chantiers de la Méditerranée at Havre. The torpedo consists essentially of two parts, namely, a float from which is suspended at the depth of about 6ft. the torpedo itself. The torpedo consists of four separate compartments. The first contains the explosive, which is exploded electrically. The second is vacant. The third contains about 6,800ft. (1¼ miles) of controlling cable wound into a hollow coil in such a manner that it pays out free from kinks. As the boat proceeds the cable pays out through the "cable tube," which guides it safely past the propeller. The fourth compartment contains a 40 H.P. motor running at 1,560 to 1,600 revolutions per minute, and geared down to 750 to 800 revolutions per minute to drive a 30in. diameter two-bladed screw with 30in. pitch. Aft of the motor is the polarised relay for actuating the rudder. The total weight ready for service is about 1⅓ tons. Two independent currents are transmitted from the shore to the torpedo by means of a concentric cable, the central conductor of which carries the steering current from a small battery, while the outer conductor carries the main current. The resistance of a cable 6,000ft. long is 6 ohms. In designing the motor, efficiency has been to some extent sacrificed to lightness and convenience. The cable absorbs 3,750 watts, and the motor 4,000 watts, or about 8,000 watts in all, that is, 10 H.P. The generator—an Edison "Municipal"—furnishes a current of 25 amperes at 1,300 volts, when running at 1,500 to 1,600 revolutions, that is, rather more than 40 H.P. The motor is two-pole, series-wound, and drives the torpedo over 21 miles an hour. Immediately the torpedo is arrested by coming against a vessel the fact is shown on the ammeter in the circuit. The firing key is then pressed and the charge exploded.

Electricity in Ships of War.—The extent to which electricity is employed in modern warships may be gathered from the following particulars of the electrical outfits of eight vessels recently built and armed at Elswick. In each of the three Colonial cruisers, "Katoomba," "Mildura," and "Wallaroo," the electric light installation comprises 257 16 c.p. and 37 50 c.p. lamps. Each vessel is fitted with two yard-arm reflectors, containing eight 50 c.p. lamps, and two semaphore signalling arrangements, consisting of a box fitted with a mirror reflector, which throws the light from four 16 c.p. lamps on two movable arms of a semaphore. Each vessel has three search light projectors, and a generating plant consisting of two combined sets of "Willans" engines and "Siemens" dynamos, running at 415 revolutions per minute, and giving 300 amperes at 80 volts. The torpedo-tubes in each ship are fired electrically, and the eight 4·7 inch quick-firing guns are also fitted with two alternative methods of electrical firing. In the four smaller Colonial war vessels, recently completed by the same firm, internal electric lighting has not been considered necessary, but each has been fitted with a "Tower" engine and Siemens 80-unit dynamo to supply current to the projector, yard-arm reflector, and semaphore reflector. Each has, moreover, five torpedo tubes, fired electrically from the conning tower, and two 4·7 guns, also fired by electricity. In another recently-completed cruiser of Elswick build, the "25 de Mayo," the electrical outfit consisted of three Parsons steam turbine 16-unit dynamos, supplying current to 190 16 c.p. and 12 50 c.p. lamps, yard-arm reflectors, search-lights, &c. The torpedo tubes are also fired electrically, as well as the two 21cm. guns and the 8 4·7in. guns, while the sights are illuminated by minute incandescent lamps for night service. All these vessels are wired on the double wire system, with lead-cased cable, on the plan originally introduced at Elswick, and the whole of the work was carried out by the Elswick Electrical staff, under the superintendence of Mr. L. Newitt, with Mr. A. A. Campbell Swinton as electrical adviser.

MAGNETISM IN IRON AND OTHER METALS.*—XL.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 292, Vol. XXVI.*)

§ 141. Effects of Combined Pull and Torsion on the Magnetisation of Iron and Nickel.—The same observers have recently examined, in much detail, the changes of magnetism in iron and nickel, which occur when a rod is subjected at the same time to pull and twist, and Nagaoka has also determined the curves of magnetisation which are given by nickel wires when kept in this complicated condition of stress. Many of the results are of great interest, and space must be found for a brief notice of some of them here.†

In the magnetisation of any of the magnetic metals we may distinguish broadly between three successive stages in the process. There is first the early stage, during which the susceptibility is comparatively small: the curve of magnetisation shows at the beginning a comparatively easy gradient. Then there is

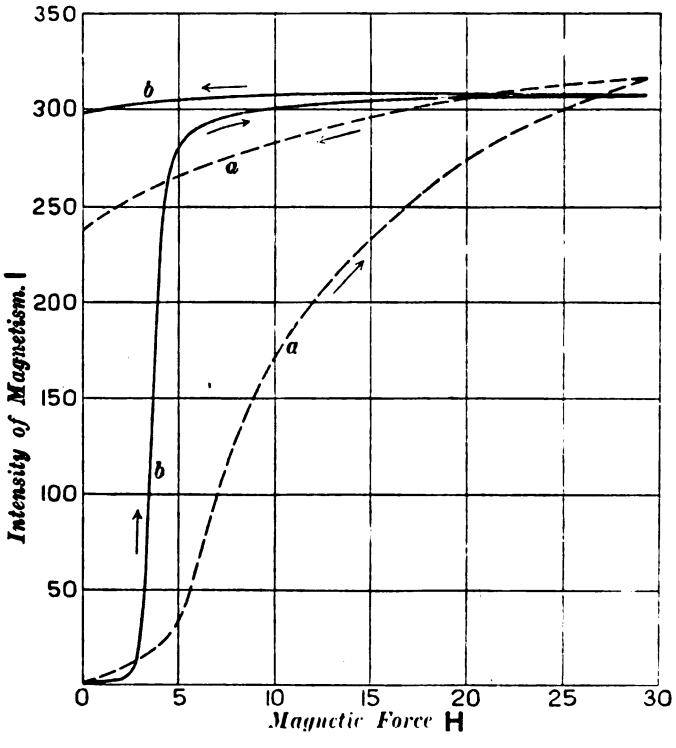

FIG. 120.—Magnetisation of Nickel, *a a*, without torsion ; *b b*, with torsion.

the middle stage, a stage of high susceptibility, when the curve has bent upwards and rises rapidly towards the "wendepunct." Lastly, there is the third stage, in which the condition of the specimen may be spoken of, rather loosely, as nearly saturated. In the third stage the curve has passed the "wendepunct," and has again taken an easy gradient: the susceptibility rapidly diminishes.

In specimens which are free from stress during the process of magnetisation these three stages are to some extent blended, but are still fairly distinguishable, as a reference to any of the figures which have been given for iron, steel, nickel, or cobalt will show. By applying torsion, and still more by applying both torsion and longitudinal pull, it is possible to differentiate the stages to a very remarkable degree. This is shown by Nagaoka's experiments on nickel wires, which are illustrated in the following figures.‡

Fig. 120 shows the influence of simple torsion. The curve *a a* is the ordinary magnetisation curve of a long nickel wire, annealed and tested (without torsion) by applying and removing a magnetising force of about 30 C.-G.-S. units. The curve *b b* was taken while the wire was held twisted, the amount of the twist being 3° per centimetre of length.

As the diameter of the wire was 1 millimeter, the amount of twist corresponds to an angle of shear of $\frac{3 \times \pi \times 0{\cdot}05}{180}$, or 0·0026 radians at the circumference, where the shearing strain is greatest.

The curve taken when the wire was under torsion exhibits some striking differences from the other. In the first place, the initial susceptibility (with respect to feeble magnetic forces) is greatly lowered by torsion. The first part of the magnetising process is sharply distinguished from the second stage. When the second stage is reached, the twisted wire has very great differential susceptibility. Again, the "wendepunct" in it is comparatively sharp. Finally, by comparing the curves got during the removal of magnetising force, we see that the twisted wire possesses much more retentiveness than the other; the ratio of residual to induced magnetism in it has the remarkably high value of 0·97, whereas in the untwisted wire the same ratio is only 0·75. If the comparison of residual magnetisms were made at earlier points in the magnetising process, this difference would be still more marked.

Mr. Nagaoka's experiments further show that when the angle of twist is considerably increased the curve shows a slight tendency to revert towards the normal type (for untwisted wire). It must, however, be borne in mind that any large amount of torsion complicates the conditions of the experiment by making the strain pass the limit of elasticity.

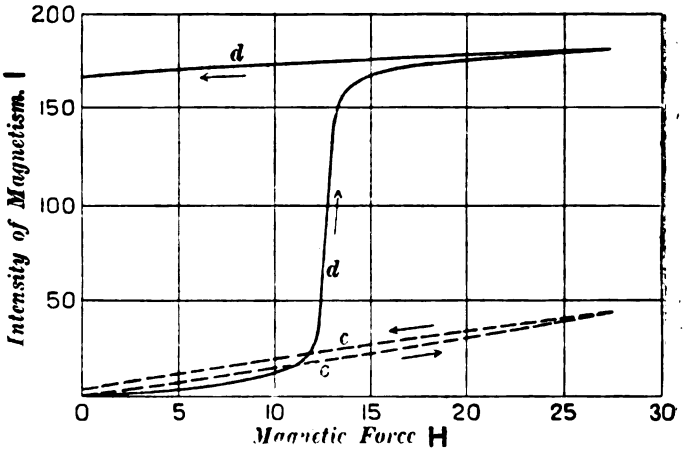

FIG. 121.—Magnetisation of Nickel, *c c*, with longitudinal pull only ; *d d* with longitudinal pull and torsion.

More curious still are the results of combining torsion with longitudinal pull. The application of pull, by itself, has (as was shown in § 121) the effect of lowering the magnetisation curve in nickel. When twist is superposed upon pull the initial part of the curve is still further lowered, but at a moderately great value of the magnetising force a sudden change takes place, the differential susceptibility becomes enormous throughout a narrow range of values of the magnetising force; then comes a somewhat sharp "wendepunct," and the second stage is followed by a third in which there is a slow approach to saturation. Fig. 121 is selected from Nagaoka's curves to illustrate these effects. The wire, which was the same specimen of nickel as before, was loaded with 10 kilos., and the curve *c c* was taken while there was no twist. Here, as the results of § 121 lead us to expect, there is low susceptibility throughout and exceedingly little retentiveness. Next, a twist of 3° per centimetre was given to the loaded wire. The curve of magnetisation was then found to take the extraordinary form shown in *d d*, with reduced initial susceptibility, which lasts through a wide range of force,—followed by an abrupt rise of magnetism in a field of about 12 C.-G.-S., and then high retentiveness. We have here a quite exceptionally sharp definition of the three stages in the magnetising process, and a singularly striking display of hysteresis. The curves of

Figs. 120 and 121, relating, as they do, to the same specimen, form one group; they are, moreover, drawn to the same scale. *a a* is the normal curve, showing the behaviour of the metal when there is neither pull nor twist. *b b* shows

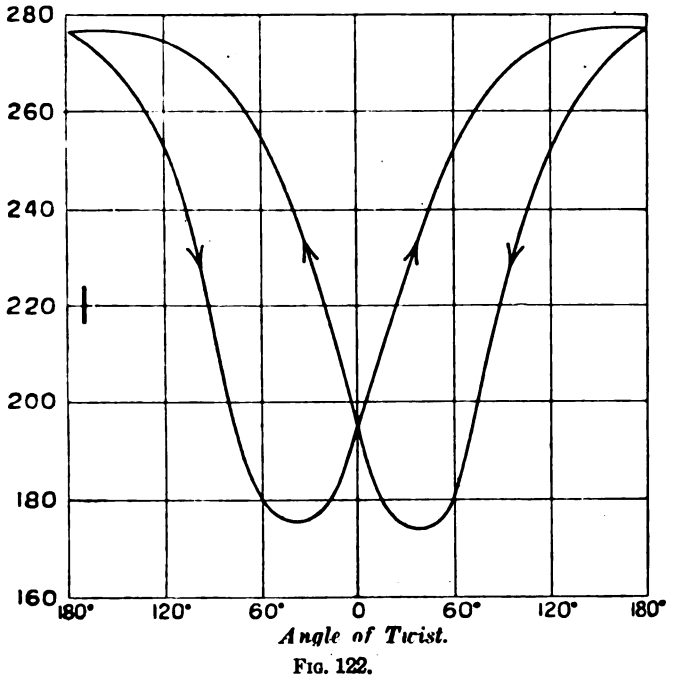

FIG. 122.

the effect of twist alone. *c c* shows the effect of pull alone. Finally, *d d* shows the effect of combining the twist of *b b* with the pull of *c c*. It is interesting to notice that the whole

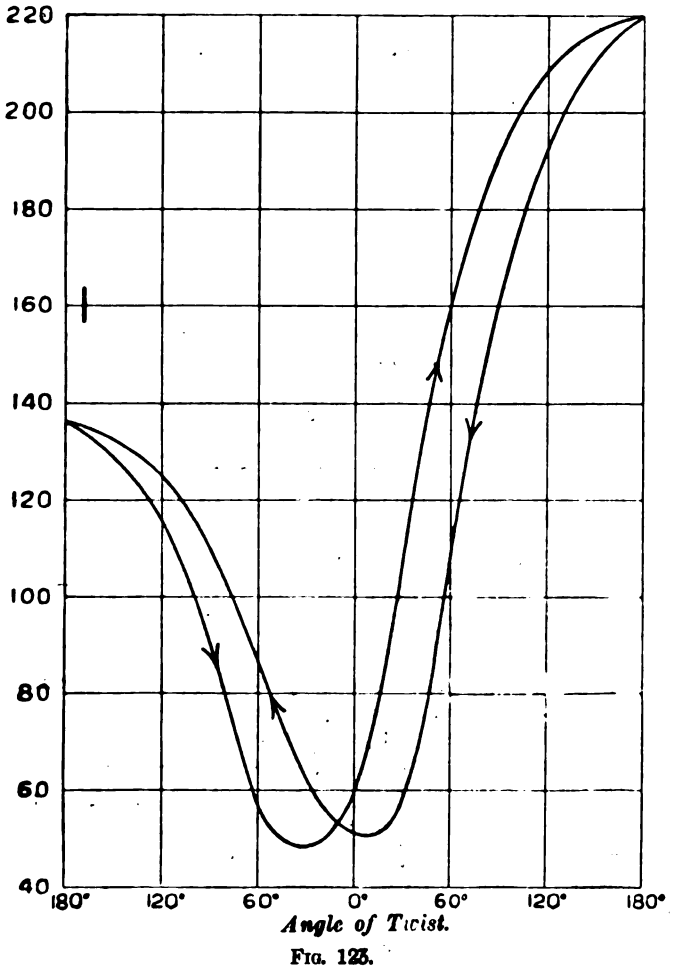

FIG. 123.

amount of magnetism which is acquired during the second or abrupt stage in *d d* is only about half the amount that is acquired during the corresponding stage in *b b*.

The effects of twist which these curves exhibit do not seem capable of explanation by reference to the development of magnetic aeolotropy in consequence of the pull and push components of torsional stress. The inadequacy of this explanation will be even more apparent in the experiments with which the next paragraph deals.

§ 142. Effects of Cyclic Twisting in Nickel, when associated with Longitudinal Pull.—The combination of torsion and pull has been found by Nagaoka to have an even more extraordinary effect on the magnetisation of nickel if the torsion be subjected to cyclic reversals, while the pull is maintained constant.

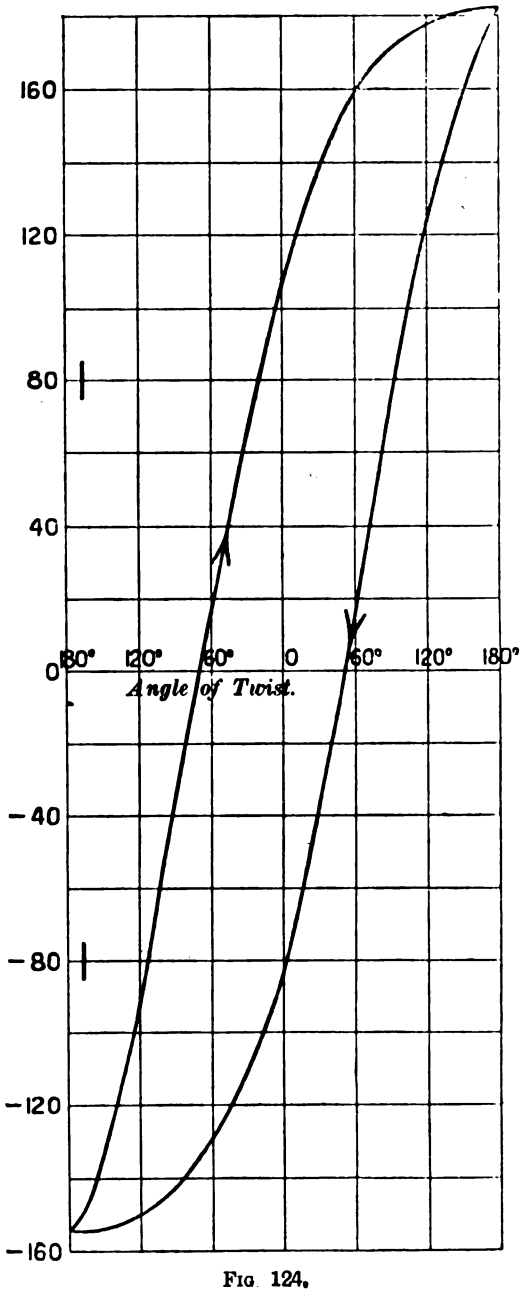

FIG. 124.

Let a nickel wire be exposed to any moderately weak magnetising force in the direction of its length, and let one end be twisted to and fro while the other end is held fixed. So long as there is no longitudinal pull the effects of this alternating torsion are comparatively simple. The curve connecting magnetism with angle of twist has a symmetrical, or nearly symmetrical, form, recalling that found in iron (Fig. 114), but with the important difference that, in nickel, the magnetism increases with twist instead of diminishing as it does in iron. This difference is intelligible enough, in view of the opposite effects of pull in nickel and in iron.

But let the experiment be repeated when a weight is hung from the wire to produce longitudinal pull. It is now found

Digitized by Google

that the symmetry of effect is gone. The magnetism is much increased by twisting the wire to the side towards which the earliest twist is directed. Twisting to the other side does not increase the magnetism nearly so much. And if the amount of pull be sufficiently increased, this want of symmetry becomes more pronounced, until a very peculiar result is brought about—that, whereas twisting towards one side increases the magnetism, twisting towards the other side decreases the magnetism, and *may even decrease it so much as to reverse its sign.*

This description will become more intelligible if reference is made to Figs. 122, 123, and 124, which illustrate one of Nagaoka's experiments. The specimen of nickel was a wire 1 mm. in diameter and 40 cms. long, tested in the annealed state. A surrounding solenoid allowed a magnetising force to be applied, which was kept constant with the value 2·47 throughout the experiment. In the first instance (Fig. 122) there was sensibly no longitudinal pull. Repeated twistings from $+180°$ to $-180°$ brought about a cyclic state of things which is represented in the figure. Here the general effect of torsion is that twisting to either side augments the magnetism. Next, a longitudinal pull was applied, amounting to 1·45 kilogrammes per square millimeter, and the process of twisting was repeated. The result was to establish the cycle of Fig. 123, in which the loop of the curve on the side of positive twist is much more prominent than the loop on the side of negative twist. The term positive, as used here, simply distinguishes the direction which happened to be given to the twist in the first instance. The question of which direction of torsion augments the magnetism most depends simply on which is the direction the wire is first twisted in. Next, the longitudinal pull was increased by adding more steady load, and it was found that the positive loop of the curve lengthened, while the negative loop became more insignificant. Finally, the negative loop disappeared, and with a load of 7·82 kilogrammes per sq. mm., the cyclic process took the form shown in Fig. 124, where there is the extraordinary phenomenon of a reversal of magnetic polarity occurring with every reversal of torsional strain, notwithstanding the fact that the force H of 2·47 units was continuously operative in one fixed direction.

It is clear that these effects of twist are not consequences of aeolotropy in the magnetic susceptibility of the twisted material. In fact, the inducing magnetic force plays a very subordinate part in the changes of magnetism which take place when the wire is twisted to and fro, after a cyclic régime is established. Its function is to set up a magnetic condition to begin with; then, as the wire is twisted back and forth, there is with each twist a profound change in the molecular configuration. This is the direct result of the twist, and may, as in the case last described, go so far as to produce reversal of magnetic polarity.

When the magnetising field is sufficiently strengthened, this reversal of polarity does not occur. The inducing force then asserts itself, and the effects of twist come to be more nearly such as might be anticipated from the consideration of aeolotropy. Iron does not reverse its polarity under the combined influence of pull and twist.

LIGHTNING CONDUCTORS.

BY DR. OLIVER LODGE.

(Continued from page 754, Vol. XXVI.)

Calculation of the Effect of Radiational Dissipation of Energy on the Length of the B Spark.

§ 63. In order to see whether the suggestion made in the last paragraph, that the effect of iron cores may be to increase the radiational dissipation of energy by the circuit, let us see what the effect of this term is in general. The rate at which a discharging condenser loses its energy by radiation may be expressed in terms of a dissipation resistance coefficient, extra and added to any resistance which the metals of the circuit may have. Call this resistance ρ, then the rate of loss of energy at any instant is

$$\frac{d\left(\frac{1}{2}\,S\,V^2\right)}{dt} = \frac{V^2}{\rho} = \frac{V^2}{3\,\mu\,v\left(\frac{L}{\mu\,l}\right)^2},$$

the last term being obtained in the *Phil. Mag.*, July, 1889, p. 56; l being the length of the circuit, L its inductance, and $\mu\,v$ being 30 ohms.

This conclusion is independent of the capacity of the jars; for, while the rate at which a discharging circuit loses energy depends only subordinately on the circumstances of the conducting portion, so long as it has a simple open contour,[1] it depends not at all on the capacity of the condensing portion.

But though the loss of energy per second is independent of the capacity of the jars used, the *proportionate* loss of energy, on which damping depends, is very much otherwise. For the potential-amplitude at any instant falls exponentially thus

$$V = V_0\,e^{-\frac{t}{S\rho}},$$

and the damping coefficient effective in these alternative path experiments is just this same exponent factor, with t equal to a quarter period or $\frac{1}{2}\pi\sqrt{(LS)}$.

Hence, the extra or radiational damping term is

$$e^{-\frac{\pi}{2\rho}\sqrt{\frac{L}{S}}} = e^{-\frac{\pi\,\mu\,v}{2\rho}\sqrt{\frac{L/\mu}{S/K}}} = e^{-\frac{\pi\,\mu^2\,l^2}{6\,L^2}\sqrt{\frac{L/\mu}{S/K}}}.$$

§ 64. To find what sort of value this term has in ordinary open circuits without iron, we can refer back to the experiments recorded in Vol. XXIII., page 164. The values of S for the cases there treated were—

For the gallon jars (§ 49)	2,890 K centimetres.
For the pint jars (§ 46).....	670 K centimetres.
For the Voss jars (§ 41).....	143 K centimetres.

The self-induction varied with the alternate path and with the three positions of the discharger (Fig. 9). Its smallest value

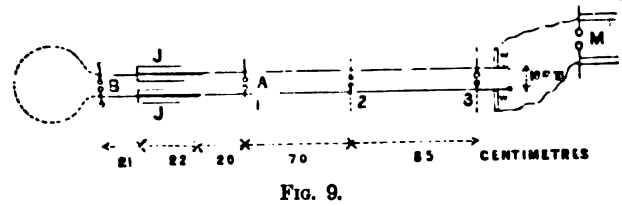

FIG. 9.

for the No. 2 wire and No. 1 position is $2{,}230 + 1{,}290 = 3{,}500\ \mu$ centimetres, or, say, as follows:—

Values of L/μ, *in Centimetres.*

—	Position 1.	Position 2.	Position 3.
Thick wire paths	3,600	5,000	6,700
Medium paths	4,600	6,000	7,700
Thinnest (No. 40) path	5,500	6,900	8,600

So the values of $\sqrt{\left(\frac{L/\mu}{S/K}\right)}$ are about

8 for the thinnest wire, smallest jars, and No. 3 position.
5 for the thick wire, smallest jars, and No. 1 position.
3½ for the thick wire, pint jars, and No. 3 position.
1½ for the medium wire, gallon jars, and No. 2 position.

In none of the cases is this term bigger than 8. As to the value of l, we may suppose that to be about 10 centims only, if we measure it from jar to jar, as the effective length of a horseshoe magnet is measured; and in that case $L = 500\,\mu\,l$. But even if we took it as the whole length of the circuit, so that $L = 10\,\mu\,l$, the radiational resistance would still come out 9,000 ohms, or much too big for the radiational damping term to have any appreciable effect in these particular cases.

This teaches us that while radiation is the principal way in which small linear oscillators like Hertz vibrators get rid of their energy, it is otherwise with our closed circuits with

Digitized by Google

electrostatic ends close together, and therefore of great capacity. These dissipate the greater part of their energy by heating the wire; the waves they emit are very long, and the portion of wave broken off and abandoned to space contains but a small fraction of the total energy.

§ 65. Hence, for an explanation of the fact noticed in § 48, that the B sparks from small jars fall below their calculated value, we must look, not to their larger radiation damping term as there suggested (because, though it is larger for small jars than big ones, it is not large enough to be effective), but to the fact that the electrostatic capacity of the B portions of wire has in the calculation been ignored. The capacity of these wires is not unusually enough to have any appreciable influence on the discharge of large jars, but with small ones an appreciable fraction of their relieved charge is occupied in charging up the B leads, and hence the energy of its rush is diluted. That seems to me now the most probable explanation of the very satisfactory agreement with theory shown by large jars, and of the distinctly defective vigour of small ones.

Experiments on the Deflagration of Different Wires.

§ 66. To see how the material of a lightning conductor affects its liability to be destroyed by a flash, a set of exceedingly fine wires supplied by Johnson and Matthey, all of the same diameter, of gold, silver, platinum, and iron, were employed. A scrap of each was laid down on a 4in. glass plate in four parallel lines, between two tinfoil strips, so that the length of each wire was 1·5 centimetres. A number of such plates were prepared. One of the large glass condensers was employed, capacity ·02 microfarads, and the four wires were arranged in its circuit.

Four Wires Parallel.

Spark length of discharge sent through them.	Result.
10 millim.	All four wires deflagrated.
5 „	ditto
1 „	No effect on any.
2 „	Silver deflagrated and smeared on the glass. Copper disappeared bodily, without deposit. Iron and platinum uninjured.
Another plate, 1·5 millim. ...	Silver melted at one end. Copper oxidised. Other two intact.
Same plate, repeated, 1·5 mil.	Copper disappeared with very slight trace. Iron and platinum remain.
Same again, 1·5 millim.	Platinum is deposited in small globules. Iron all right.
Same again, 1·5 „	Iron deflagrated and broadly dispersed.

This is typical of what happened in many trials. When in parallel the best conductor took most of the discharge and was most damaged. The iron having much the highest throttling resistance took very little, until there was no other path open. Even platinum got destroyed before iron.

When the wires are in series, however, so that the same current has to pass through all, the order of their disappearance is inverted, and the iron is distinctly more heated than the others.

Four Wires End to End.

Spark length.	Result.
2 millims.....	Platinum melted into globules. Iron deflagrated; other two uninjured.
Another plate, 1 millim.....	Platinum broken in two near the middle. Iron has evidently been very hot, but is not destroyed. The copper and silver are all right.

(To be continued.)

Atmospheric Electricity.—M. Vaussenat, Director of the Observatory on the Pic du Midi, in order to diminish the electrical potential of storm clouds and prevent the formation of hail, has crowned the crests of the hills around Tarbes, where storms are of regular occurrence, with masts supporting conducting rods. According to the *Bulletin International de l'Electricité*, this device has proved successful.

THE MEASUREMENT OF ELECTRIC POWER GIVEN TO AN INDUCTIVE CIRCUIT.*

BY DR. J. A. FLEMING.

The ingenious method proposed by Messrs. Swinburne, Ayrton, and Sumpner for the measurement of the electric power given to any circuit by any electric current, by means of three voltmeters, is one which, whilst perfect in principle, presents certain practical difficulties in general application.

Suppose, for instance, it is desired to measure the power taken up in the whole of the transformers connected to a transformer station when under light load, and that this has to be done without interfering in any way with the lighting work. In carrying out the measurement, in accordance with the proposed method, it would be necessary to provide a non-inductive resistance capable of carrying the whole current sent out from the station, and which preferably should have such a magnitude that the drop in volts over this resistance should be about equal to the ordinary drop in volts across the primary mains of the transformer station, or, at any rate, not be very different in amount. The alternator would then have to be excited to an electromotive force, higher than the normal, so as to maintain the proper volts between the primary terminals of the transformers. It might be, and generally would be, impracticable to make these arrangements, and the proposed method would, therefore, be inapplicable in such a practical case. It is possible, however, that a modification of this method can be made which will be applicable to such cases, and will enable transformer tests to be made on working primary circuits without interfering with the E.M.F. of the alternator. It is as follows:—Let x (Fig. 1) be an inductive circuit, and let y

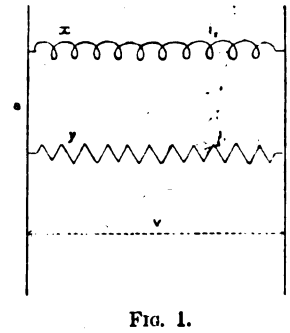

FIG. 1.

be a non-inductive circuit joined in parallel with it between two mains, a and b, between which a potential difference is maintained, which at any instant has the value v. Let i be the current in the main circuit at that same instant, and let i_1 and i_2 be the currents in the non-inductive and inductive circuits y and x also at the same instant; then we have always,

$$i = i_1 + i_2 \quad . \quad . \quad . \quad . \quad . \quad . \quad (1);$$

hence,

$$i^2 = i_1^2 + i_2^2 + 2\,i_1\,i_2 \quad . \quad . \quad . \quad . \quad . \quad (2).$$

Let r be the resistance of the non-inductive circuit y, then

$$i_1\,r = v \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3).$$

The power w taken up in the inductive circuit x at that instant is given by

$$w = v\,i_2;$$

hence,

$$w = i_1\,i_2\,r \quad . \quad . \quad . \quad . \quad . \quad . \quad (4).$$

Hence from (2) and (4)

$$i^2 = i_1^2 + i_2^2 + \frac{2\,w}{r} \quad . \quad . \quad . \quad . \quad . \quad (5);$$

or,

$$w = \frac{r}{2}\left(i^2 - i_1^2 - i_2^2\right) \quad . \quad . \quad . \quad . \quad (6).$$

This last equation is true at any instant, hence the mean value of the power, W, taken up is obtained by integration of this equation (6), and is

$$\int_0^T w\,dt = \frac{r}{2}\left(\int_0^T i^2\,dt - \int_0^T i_1^2\,dt - \int_0^T i_2^2\,dt\right);$$

* See *The Electrician*, April 17, 1891, p. 736; also *Industries*, March 27, 1891, p. 306.

Digitized by Google

or, $$W = \frac{r}{2}\left(I^2 - I_1^2 - I_2^2\right). \quad . \quad . \quad . \quad . \quad . \quad (7),$$

where I_2, I_1, and I are the readings of dynamometers inserted in the respective circuits x, y, and the main.

To reduce this method to practice, arrange matters thus:—Let T (Fig. 2) be the transformer or transformers on the working circuit, and of which we wish to measure the power taken up in the primary circuit, P. Put a dynamometer, or alternate-current ammeter, a, on the primary circuit, and arrange two others, b and c, as shown in Fig. 2. Let c have a non-inductive resistance in series with it (which may be a water resistance) across the mains. Arrange also a voltmeter, V, across the primary mains to measure the potential difference between them. Then the dynamometer a measures the current I_1 going through the inductive circuit, and c measures the current I_2 through the non-inductive circuit, and b measures the total current. The quotient of the reading V of the voltmeter by the reading I_2 of the dynamometer c gives the value of the resistance r in the formula (7), and hence the power being taken up in the primary circuit of the transformer, is given by the expression,

$$W = \frac{V}{2\,I_2}(I^2 - I_1^2 - I_2^2). \quad . \quad . \quad . \quad . \quad (8).$$

The difference between this method and that of Messrs. Swinburne, Ayrton, and Sumpner is that currents are read instead of volts, and *vice versâ*, and that there is no need for making a call for more electromotive force than would be needed to operate the transformer in the usual way if the measurements were not being made.

The objection which may perhaps be raised to this modification of using the non-inductive resistance in shunt rather than in series is that the same cause of error will be introduced which vitiates the accuracy of a wattmeter reading of alternating current power, viz., that even if the circuit y is made to have as little inductance as possible, yet unless it is quite zero in that respect, the very fact of being joined in parallel with a circuit of possible large inductance will prevent the current in y from being in phase with the electromotive force v. It is

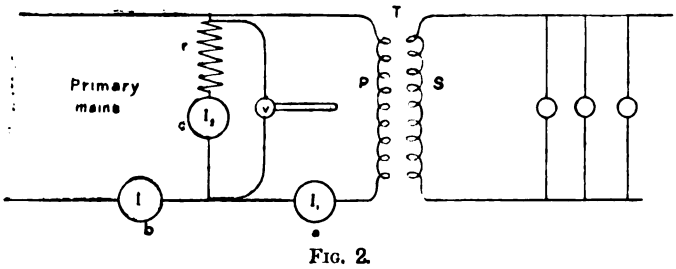

Fig. 2.

possible, however, to settle by direct experiment how far this is the case. Let the two methods, (i.) the one with three voltmeters and non-inductive coil in series, and (ii.), the one with three ammeters and non-inductive coil in shunt, be tried on one and the same highly inductive circuit, and note the difference, if any, in the power reading obtained. If there is no practical percentage of error, I think the method with the three ammeters will prove to have advantages in practice over the other. We want a means of determining the efficiency of house-transformers *in situ*, and that without disturbing the E.M.F. of the primary circuit, and the same is the case in factory tests, where it will often be practically impossible to secure the increased E.M.F. necessary for the three voltmeter method.

ON COEFFICIENTS OF INDUCTION.*

BY A. ANDERSON, M.A.

The following method of measuring the coefficient of self-induction of a coil is somewhat similar to that of Maxwell ("Electricity and Magnetism," Vol. II., Art. 778), inasmuch as a condenser is employed. But it is not a null method; and, although not absolutely necessary for rough determinations, it is desirable to use a ballistic galvanometer on account of the ease with which the throws of the needle can be observed, and because less adjustments and observations have to be made.

In Fig. 1 E is the coil whose inductance is to be found. One pole of the condenser F is joined to D, and the other to a mercury-cup r. G_1 and G_2 are mercury-cups, forming the terminals of the galvanometer, and p, q, and s are mercury-cups connected respectively with A, C, and B. A rocking-key can simultaneously connect G_1 with p and G_2 with q, or G_1 with r and G_2 with s, the galvanometer being in the former case in the branch A C and in the latter in B D, in series with the condenser. The branches A B A D are equal inductionless resistances, and D C, which is also inductionless, is adjusted till as perfect a balance as possible is obtained. When the battery-circuit is made or broken, the galvanometer being in the branch A C, there is a throw of the needle due to the passage through this branch of a quantity of electricity equal to $L\left(\frac{dc}{dx}\right)_{x=0}$, where L denotes the coefficient of self-induction of E, and c the current in the galvanometer, when an additional resistance x is put in the branch B C. The current c is equal to $E\,b\,x/\Delta$, E being the E.M.F. of the battery, and Δ the determinant

$$\begin{vmatrix} a+2R+x, & -R-x, & -R \\ -R-x, & b+G+R+x, & -G \\ -R, & -G, & b+G+R \end{vmatrix}$$

in which a is the resistance of the battery, R of the coil, and G of the galvanometer. Since

$$\left(\frac{dc}{dx}\right)_{x=0} = \left(\frac{Eb}{\Delta}\right)_{x=0},$$

we easily find

$$\left(\frac{dc}{dx}\right)_{x=0} = \frac{Eb}{(b+2G+R)[a(b+R)+2bR]},$$

and therefore the quantity of electricity is

$$\frac{LEb}{(b+2G+R)[a(b+R)+2bR]}.$$

If, by means of the rocking-key, the galvanometer be put in B D,

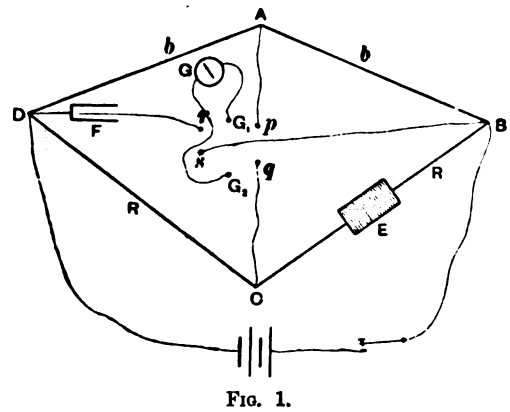

Fig. 1.

and the battery circuit made or broken as before, a quantity of electricity will pass through the galvanometer equal to $K(V_1 - V_2)$, where K is the capacity of the condenser and $(V_1 - V_2$ the final difference of potential between the points B and D. If the capacity K be adjusted till the throw of the needle is the same as before, we have

$$L = K\frac{V_1 - V_2}{Eb}(b+2G+R)[a(b+R)+2bR],$$

which reduces to $$L = 2KR(b+2G+R),$$

since $$(V_1 - V_2)\left(a + \frac{2bR}{b+R}\right) = \frac{2bR}{b+R}E.$$

It may not be possible, with given values of b, R, and G, and a given condenser, to make the throws the same. R may, however, be increased or diminished by the introduction of an inductionless resistance in series or in parallel with it, and the same is true for b and G. A slight change in the formula will then be necessary. If, in this way, we find two nearly equal values of K for one of which the throw of the needle is greater and for the other less than that of the former throw, the correct value of K may be found by proportional parts. But a much better method is to use a ballistic galvanometer, in which case no adjustment of resistances beyond that of getting a perfect balance is required. The two angles of throw α and α' are simply observed, and the coefficient of self-induction is given by the formula

$$L = 2KR(b+2G+R)\sin\frac{\alpha}{2}\sin\frac{\alpha'}{2}.$$

The following determination of the self-induction of a coil may

* Abstracted from the *Philosophical Magazine*, Vol. XXXI., No. 191, April, 1891.

Digitized by Google

be given as an example. The coil was a circular coil of mean radius 20·9 centim. wound in a rectangular groove of breadth 1·894 centim. and depth 1·116 centim., and having 278 turns. The galvanometer was an ordinary reflecting galvanometer with a resistance of 164·8 ohms, the controlling magnet being placed so as to make the sensibility as great, and the time of swing as long, as possible. An inductionless resistance of 100 ohms was put in series with the coil, and the resistances of the branches A B and A D were each 10 ohms. A balance was roughly obtained by making the branch C D 150 ohms, and, in the absence of better means, an almost perfect balance by adding to C D a wire whose resistance was subsequently found to be ·51 ohm. The resistance of the branch C D or C B was, therefore, 150·51 ohms. The following numbers are the means of several readings which agreed very well together:—

Kick of needle due to self-induction of coil	= 43·208 scale-divisions.
Kick due to charge or discharge of condenser, capacity ·5 microfarad	= 46·125 ,, ,,
Kick for capacity of ·45 microfarad	= 41·875 ,, ,,

The capacity which would give a kick of 43·208 is found from these numbers to be ·4657 microfarad. The coefficient of self-induction, when reduced to absolute measure, is therefore

$$10^3 \times \cdot 9314 \times 150 \cdot 51 \times 489 \cdot 7 = \cdot 06865 \times 10^9,$$

or, in practical measure, ·06865 henry.

Null Method of measuring the Coefficient of Self-induction of a Coil.

In the method given in Maxwell (Art. 778, Vol. II.) the current through the galvanometer at any moment is zero, but the double adjustment which is necessary is inconvenient. Two methods are given by Mr. Rimington in the *Philosophical Magazine* for July, 1887; but this condition is not fulfilled, and Mr. Rimington shows this for one of his methods. Prof. Niven's methods, given in the *Philosophical Magazine* for September, 1887, do not differ greatly from those given by Mr. Rimington.

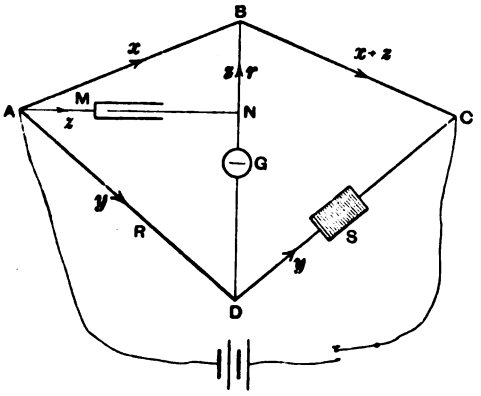

FIG. 2.

The following method, which is but a slight modification of Maxwell's, does away with much of its impracticability.

In Maxwell's method the armatures of the condenser are connected to A and B (Fig. 2), and S is the coil whose coefficient of self-induction is to be found. The only difference in the method now given is that an adjustable resistance r is placed between B and N. Suppose a balance has been obtained so that no permanent current flows through the galvanometer. This balance will not be disturbed by changing r. Let x be the whole quantity of electricity which has passed through A B at the time t, z the whole quantity which has passed through A M, and y that through A D. Then, if K be the capacity of the condenser, and if we suppose the potential of N to be always equal to that of D, we have

$$P\frac{dx}{dt} = \frac{z}{K} + r\frac{dz}{dt}$$

$$\frac{z}{K} = R\frac{dy}{dt},$$

$$r\frac{dz}{dt} + Q\left(\frac{dx}{dt} + \frac{dz}{dt}\right) = S\frac{dy}{dt} + L\frac{d^2y}{dt^2},$$

nd, therefore,

$$(r+Q)\frac{dz}{dt} + \frac{Q}{P}\left(\frac{z}{K} + r\frac{dz}{dt}\right) = \frac{Sz}{RK} + \frac{L}{RK}\frac{dz}{dt}.$$

Hence we have the conditions

$$QR = PS,$$

and

$$r + Q + \frac{Qr}{P} = \frac{L}{RK}.$$

The first is the condition for no permanent current; and the second, which is the condition for no instantaneous current, gives the formula

$$L = K\{r(R+S) + RQ\}.$$

If we make $r = 0$, we get Maxwell's formula. The practical method immediately suggested by the above expression for L is to obtain a permanent balance in the ordinary way, and then to adjust r and, if possible, K, till there is no motion of the galvanometer-needle. Or if, as in Maxwell's method, values of P, Q, R have been obtained, so that there is only a small throw of the needle when the battery-circuit is made or broken, the final adjustment may be quickly and accurately made by introducing an adjustable resistance r, and in doing this a telephone may be employed instead of the galvanometer. It is clear that, if we do this, R and Q must be such that $KRQ < L$.

It seems, therefore, advantageous to make R and P both large, and Q and r both small. Hence the very easy practical method suggested by the formula might not be so sensitive as to obtain first an approximate adjustment, and then to make the final adjustment by varying r.

The following example of the measurement of the coefficient of self-induction of a coil by this method may be given:—The resistance Q being 10 ohms, and P 100 ohms, there was a permanent balance when R was made 1577 ohms, so that S, the resistance of the coil, was 157·7 ohms. A condenser of one microfarad capacity was then placed between A and N, and the resistance r adjusted till there was no kick of the galvanometer-needle. This value of r was found to be 59 ohms, though the sensitiveness was, doubtless, not as great as might have been obtained. Substituting these values, we have

$$L = 10^3 \times (15770 + 59 \times 1734 \cdot 7) \text{ centim.}$$
$$= \cdot 118 \text{ henry.}$$

The same method was also employed to find the coefficient of self-induction of the coil described in (1) of resistance 59·51 ohms. P was made 1000 and Q 10 ohms; and when R was 5051 an almost perfect balance was obtained. Both a telephone and a galvanometer were used in the final adjustment of r, and the value thus found was 3·65 ohms. The coefficient of self-induction is, therefore,

$$10^3 \times (50510 + 3 \cdot 65 \times 5101 \cdot 51) \text{ centim.}$$
$$= \cdot 0691 \text{ henry,}$$

which does not differ greatly from the previous result.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

FRIDAY, May 8th. (To-night).

INSTITUTION OF CIVIL ENGINEERS.

7.30 p.m. Students' Meeting. Paper to be read: "Malta Dockyard Caisson." By J. WALTER BROWN, Stud. Inst. C.E.

ROYAL INSTITUTION.

9 p.m. Evening Discourse. "Liquids and Gases." By Prof. W. RAMSAY, F.R.S.

SATURDAY, May 9th.

PHYSICAL SOCIETY.

2.30 p.m. Meeting at the Cavendish Laboratory, Cambridge. Papers to be read: (1) "Some Experiments on the Electric Discharge in Vacuum-tubes," by Prof. J. J. THOMSON. (2) "Some Experiments on Velocities of the Ions," by W. C. D. WHETHAM. (3) "On the Resistance of some Mercury Standards," by R. T. GLAZEBROOK, (4) "On an Apparatus for Measuring the Compressibility of Liquids," by S. SKINNER. (5) "Some Measurements with the Pneumatic Bridge," by W. N. SHAW.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "The Artificial Production of Cold." By H. GRAHAM-HARRIS, M. Inst. C.E.

TUESDAY, May 12th.

ELECTRO-HARMONIC SOCIETY.

4.30 p.m. Annual Meeting at 28, Victoria-street, S.W.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary General Meeting. Paper to be discussed: "On Railway-Train Lighting," by WILLIAM LANGDON.

WEDNESDAY, May 13th.

OLD STUDENTS' ASSOCIATION.

8 p.m. Ordinary General Meeting at the Central Institution, Exhibition-road, S.W. Paper to be read: "Some Researches in Electro-Magnetic Induction," by ERNEST B. VIGNOLES, Member.

THURSDAY, May 14th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture. "Recent Spectroscopic Investigations," by Prof. DEWAR, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting. Papers to be discussed: (1) "On some Effects of Alternating Current Flow in Conductors having Capacity and Self-Induction," by Dr. J. A. FLEMING. (2) "Some points connected with Mains for Electric Lighting," by W. H. PREECE, F.R.S.

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing, and Printing Offices:
SALISBURY COURT, FLEET ST., LONDON, E.C.
Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co*" *All Editorial letters to be addressed to the Editor.*

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from Publishing Offices as above.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

SUBSCRIPTION RATES.

The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months	6 months.	12 months.
	s. d	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
For Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements should be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday.*

SMALL PREPAID ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1891 Edition, published on the 23rd February, 1891, consists of 900 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with well-written Biographical Notices of leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1891 should be ordered at once. Price 5s., post free 5s. 9d. Abroad postage extra. Prospectuses free

ELECTRICAL BOOKS AND PUBLICATIONS

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad*

"THE ELECTRICIAN" *Series at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING. Vol. I. Price 7s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Vol. I. Price 6s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

Several Further Volumes in Active Preparation.

NEARLY READY, IN TWO VOLUMES.

"THE ELECTRICIAN" PRIMERS.

Fully Illustrated.

Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

Cases for binding Volume XXVI., price 2/0, post free, 2/3.

SCIENTIFIC ACCURACY.

Under the half-ironical title of "Exact Science" we recently made some remarks on hasty generalisations, unsound reasoning, and the confusion wrought by incautious theorising. Students of physics as well as those of other sciences have ever been too fond of propounding theories, not being able to realise the rudimentary state of the subject under consideration, building hypotheses on little else than assumptions, and drawing conclusions, if conclusions they may be called, from most defective premises. BOYLE, one of the founders of the Royal Society, writing in 1675 on the Mechanical Origin of Electricity, observes that heating amber facilitates its electrical excitement, and adds "it is known that heat, by agitating the parts of a fit body, solicits, as it were, to send forth its effluvia, as is obvious in odoriferous gums." He supposed that electrified bodies emitted a glutinous effluvium which laid hold of, or became entangled in, the pores of small bodies in its egress, and upon its return to the body which had emitted it carried them back with it. So much of the early experimental work of this kind was merely qualitative, that the workers were, perhaps, driven to theorising by the natural desire for some result. The chemical doctrine of "definite proportions" was not established until the commencement of the present century, when quantitative analysis was not dreamed of. The physicist of to-day is fully employed with the elaborations of accurate research, the eliminations of disturbing forces, and the computation

Digitized by Google

and reduction of his results, that he not only has little time and zeal left for theorising, but his mind is likely to develop in another direction than that which is favourable to the establishment of important theories.

The refinements of scientific accuracy are not yet complete in any branch or department, but we learn this, not from any observed room for improvement in the exactness of results, but from the ever increasing devices for attaining more perfect measurements, for removing causes of error or for the application of corrections. The whole question of the influence of errors on results of scientific observations is an extremely interesting one, but it is generally wrapped up in very obscure mathematical language, dealing with mean squares, summations, and probabilities. If the same measurement be made repeatedly by one observer under similar conditions, he is justified in taking the arithmetical mean of all the readings as the most probable value of the result. But in casting an average it is easy to go on dividing and spinning out a quotient to an absurd number of figures. A young classical master, who has lately joined one of our Northern schools, was requested by the head master to send in a return of the average age of the boys in his class, and in his excess of zeal he calculated it out to half-a-dozen or more places of decimals. Engineers are as a rule content with four significant figures, though, of course, this does not imply a limiting value of 1 in 5,000 throughout their work. The old-fashioned engineer was content with a three-foot rule divided to quarters of an inch, but had a very clear idea of the difference between a driving fit and a working fit, even though this difference is hardly to be appreciated on a modern micrometer. Workshop measurements with electrical instruments may be carried out to-day with any tolerably good instruments to one-half per cent. There is no difficulty in getting one-quarter per cent. with first-class ammeters and voltmeters. It is perfectly justifiable, then, to use four figures if the mean of several observations be taken, but more than four would be of little use. With the apparent error, the mean error, the probable error of the mean, and the reciprocal of its square, *i.e.*, the theoretical weight, engineers very rarely trouble themselves. The scientific man may or may not satisfy himself in private as to the degree of accuracy of his work by determining the errors, but he seldom publishes their value, and life is not long enough for the general application of the method of least squares to ordinary experimental research.

The graphical method of plotting the results of observations on squared paper has been warmly welcomed by engineers, and especially by electrical engineers. The popularity of the method dates approximately from the commencement of electrical engineering, say eleven years ago, when, for want of anything but the expensive "section paper," one had to send to the Continent for the cross-ruled, but not always evenly spaced, paper, which is so commonly used abroad. But it is very remarkable that, although the plotting and drawing of curves of all kinds is so common, little or no advance has been made in dealing with the curves when they have been obtained. No sooner were the characteristic curves of dynamos obtained, than blind attempts were made to find a formula to fit them. Curve tracing is a well-established branch of pure mathematics, but few writers have troubled themselves to discuss the opposite process of curve reduction. There are one or two recognised methods which are suitable for special cases, such as in the simpler forms of harmonic analysis and the computation of the orbits of double stars, but no attempt has been made to treat the subject generally. We do not intend to enter on this occasion on the advantages of curve plotting, but merely wish to point out that an investigation is not complete when a curve has been obtained, and to urge upon mathematicians the great want which exists of *simple* directions for differentiation and reduction of the results into some more or less simple formula or law.

The latest communication that has been made on this subject tends rather to show the limited use of the methods which we have been advocating. Mr. S. Lupton, in the current number of the *Philosophical Magazine*, attacks Prof. Pickering on his laborious research on the hydrates of sulphuric acid. Criticisms while the work was in progress had already been made by Dr. Oliver Lodge and by Arrhenius, and Mr. Lupton acknowledges that the task to which he has applied himself is both ungracious and difficult. He has so many objections to make to the employment of this method for the purpose in question that it is difficult to describe the matter in a few words. The results of experiments were plotted, and curves were drawn through the points. It would seem that the accuracy of the observations was in some cases greater than the accuracy of the graphical method, and it is argued that the process of smoothing the curve by differentiation introduces additional personal error. Mr. Lupton concludes that at all events "in the case of experiments of such extreme delicacy it seems preferable to throw over the graphical method altogether and tabulate the finite differences . . . more especially as they afford a test of how far it is safe to carry the reduced results."

The question resolves itself, then, in this particular research into the magnitude of the mean error of the observations. A number of very useful hints are to be found in the non-mathematical parts of Mr. Lupton's paper, and they need but little modification to make them of great service to those who prefer graphical methods to analytical calculations. The examination of their errors deserves the attention of careful experimentalists, and they would do well to work out occasionally the probable error not only of sets of readings, but of the main result of their work. They might be saved from propounding statements about the significance of small quantities if these turned out to be of the same order of magnitude as the errors.

REVIEWS.

Revision or Examination Sheets—Machine Construction and Drawing. By A. Godfrey Day, A.I.Mech.E, Science Master Technical School and Midland Institution, Birmingham. Edited by E. J. Cox, F.C.S., Head Master Technical School, Birmingham. (London: Percival and Co.)

These appear to be specimen examination papers. It is stated on the back that "the failure of students to pass the May examinations of the Department of Science and Art frequently arises, not so much from want of knowledge of the subject-matter as from a want of familiarity with examination papers and careful practice in examination questions under the guidance of a teacher." A more clear statement of the vicious circle in which the cramming system works has seldom been made. Are examiners made for students, or students for examiners? It is here, in fact, confessed that the examiners are frequently so incompetent, or that the system of the Department is so ill devised, that the "knowledge of the subject-matter" possessed by the students cannot be properly ascertained by the present examinations. There does not seem, according to the author and editor of these papers, to be any need for the examiners to make any change, but it is suggested that the students, *after they have acquired* a "knowledge of the subject-matter," should go in for a course of study of the tricks of examinations. We notice in the illustrations that one of the first principles of machine design, viz., the rounding of the corners of castings, is frequently ignored.

Practical Perspective. By J. SPENCER, Head Master of the Science Department, Technical College, Bradford. (London: Percival and Co., 1891.)

The scholastic mind having been trained to regard geometry as an excellent educational subject, and "Euclid" as an ideal text-book for teaching the same, is tempted to mould all other cognate subjects into the same lines. The practical requirements of technical education include the study of perspective, and instead of treating the subject in a practical way, a number of books which have recently appeared, have dealt with it in the driest and most involved style. Every engineering draughtsman should have some knowledge of perspective, though he may rarely use it. The rules are extremely simple, and it is one of the few subjects which may easily be thoroughly and completely mastered by any person of ordinary intelligence. The present book is written avowedly for the requirements of certain examinations. It makes no attempt to introduce the principles in simple language, and is needlessly complicated. It may be useful for cramming for the examinations, but cannot be recommended to engineers or draughtsmen, unless for the worked examples at the end.

Traite Elementaire d'Electricite. J. JOUBERT. Deuxiéme edition. G. Masson, Paris, 1891.

This well-known text-book, which first appeared in 1888, had practically dropped out of use in consequence of the rapid developments of electrical science. The present edition has been considerably enlarged, and the theory of alternate currents is dealt with. As in most text-books of this calibre, dynamos, &c., are dismissed in a very few pages, and though this may be justifiable, the examples given ought to be well up to date. The only transformer described is one of the Gramme ring type. The author alludes to the term hysteresis, but prefers "*retard d'aimantation*," or simply "*retard*," which, in his opinion, expresses the same idea with all needful precision, and appears to fulfil all the requirements. We naturally turn to the chapter on alternate currents, for his rendering of "lag," and we find the word "*retard*" again used, a striking example of the poverty of the French vocabulary. Like all other text-books more than 10 years old, this needs severe pruning.

Les Theories Modernes de Electricite. Essai d'une theorie Nouvelle. O. LODGE. Traduit de l'Anglais et annoté par E. MEYLAN. (Gauthier-Villars: Paris, 1891.)

Under this title Dr. Oliver Lodge's well-known "Modern Views" is hardly recognisable. The translator's notes do not call for much remark. He omits to give Dr. Lodge's footnote to his remark on p. 164 (English edition), and appends one of his own, in which he observes that the effect of hysteresis is far from being negligible.

Colour Measurement and Mixture. CAPT. ABNEY, F.R.S. Romance of Science Series. S.P.C.K., London.

If excuses were needed for our noticing this interesting book, other than its own merits, it might be said that optics are a branch of electrical science. The subject of colour has hitherto been dealt with scientifically by only two writers, Ogden Rood and Church. Captain Abney's careful researches have now enabled colours to be accurately specified, so that a dyer could receive an order by telegram.

SPENDING WORK ON THE ETHER.

BY S. TOLVER PRESTON.

Doubtless it will be seen at once, on rejecting the assumption of "force" propagated to a distance without time, that if molecular "attraction" be an electrical stress or any action brought about by the ether pressure, then since "chemical action" (involved in the oxydation of the food) is known to be the receptacle whence the energy of the human body is drawn, it follows that the work expended in separating two electrically charged masses, or a keeper from a magnet, when done by the human body, must be a cyclical process, where energy passes from and to the ether simultaneously—from in the oxydation of the food, and to in the act of separating the two electrically charged masses.

If, then, by any invented device whatever, we could avoid the performance of work in the process of separating (to a distance) the electrically charged masses, or the keeper from the magnet, the conditions as far as the ether is concerned would remain the same as before; for no energy would then pass from and to the ether in the process of separation, which obviously amounts to the same as when equal energy passes from and to (*i.e.*, in the case where work is expended in separation). For we see that in both cases (work and no work) the energy of the ether is unaltered by the process. Hence it must be perfectly obvious that the work performed in separating two electrically charged masses, or a keeper from a magnet, is completely superfluous or serves no practical object whatever, if only a device could be invented to avoid spending work on the ether (or the ether coming into play in the process of separation). It is only the notion of a mysterious unchangeable and unapproachable "force" ("action at a distance") that has led to the idea that it is against theory to attempt to elude the exchange of work in such processes, and also to the further idea that energy is (by the process of separation of the masses) "stored up" in some occult non-material form, for the eventual approach of the two electrica ly charged masses, and, therefore, that the work spent in separating the masses is an abstract necessity—a sort of necessity doctrine therefore. There may be a tendency too much to overlook the fact that electric, also magnetic "attraction" is an ether stress, and that the attempt to operate upon the palpable ether, with the view to elude work that can serve no purpose at all, is a very different thing from trying to imprison the phantom "force."

A FEW CALCULATIONS ON ELECTRICAL SHOCKS FROM CONTACT WITH HIGH-PRESSURE CONDUCTORS.*

BY MAJOR P. CARDEW, R.E.

In connection with the public supply of electrical energy in which very high pressures are used, it is important to investigate the amount of shock to which persons may be exposed by contact with one conductor under various conditions of insulation and electrostatic capacity of the conductors. Serious attention is now being directed to the effect upon the human organism of shocks with steady, intermittent, or alternating currents, and the necessity for exact electrical measurement in such investigations is fully recognised.†

The present opinion upon the subject may be stated to be, roughly, as follows:—The effect of an electric shock produced by the passage of a current through the body during an appreciable time is probably proportional to the square of the current, as regards injury by destruction or heating of tissue, with all kinds of currents; while alternating and intermittent currents produce, in addition, effects upon the nerves and nerve-centres which may be directly injurious in themselves, and are generally indirectly so by producing temporary paralysis, and thus depriving the recipient of the power of terminating the period of contact.

The resistance opposed by the body to unidirectional and to alternating currents of the ordinary frequencies appears to be different, at any rate for low electrical pressures, that with the former being considerably the higher; but this difference diminishes as the pressure is increased, and is probably an effect of polarisation in the tissues.

This resistance is also largely affected by the extent of surface of the body through which the current enters, and the condition of the skin.

Without dealing further, however, with the effect produced, the following calculations merely give the current, or discharge through the body, under different conditions; the electrical impedance to the flow to earth through the body, including the resistances at the point of contact and in the earth connection, being taken as a constant resistance—r for continuous, and r' for alternating currents. The charging source is considered to be in all cases perfectly insulated, of negligible electrostatic capacity, and of ample power to maintain the pressure under all conditions.

* Paper read before the Institution of Electrical Engineers, April 23 1891.

† *Vide* the Papers by Messrs. Stone, Newman Lawrence, and Harries.

Digitized by Google

The principle upon which the following calculations are based is, that every electrical machine must at any instant, or during any time, however extended, produce equal quantities of what used to be called "positive" and "negative" electricity.

This fact is as true of a dynamo as of a piece of sealing-wax and its rubber; the emission from the source, whether it be a steady current or a small charge, is equal from the positive and negative pole. Thus, if one pole be connected to a conductor of large capacity, it will necessarily be at a potential nearer to the earth than the other pole, if the latter be connected to a conductor of smaller capacity, and the whole system thoroughly insulated; and in every case this principle determines the potentials from earth of any electrified system, leaving out of question any extraneous charge imparted to it.

The first case to be considered is that of two perfectly insulated conductors, A and B, of considerable cross section, and capacities K and K', kept charged to a steady difference of potential V. The mutual electrostatic induction is assumed to be negligible, and in general will be so, as the conductors are separated by some distance.

The potential of the earth will differ from that of A by an amount $\frac{K'V}{K+K'}$, and of B by an amount $\frac{KV}{K+K'}$, and there will be equal charges on the conductors.

If now a person making good earth with some part of his body touches conductor A with another part, the transmission through him will be not only the charge on A, but the equivalent of the opposite sign to the additional charge flowing to B to raise its potential to V. Thus the quantity that will pass through him will be

$$\frac{KK'V}{K+K'}+\left(K'V-\frac{KK'V}{K+K'}\right)=K'V.$$

The emission from the source being again equal in the two conductors, and amounting to

$$K'V-\frac{KK'V}{K+K'}=\frac{K'^2V}{K+K'},$$

the maximum current through the body will be

$$\frac{K'}{K+K'}\times\frac{r}{V}.$$

Similarly, if contact be made with B, the quantity in the discharge will be K V, the emission from the source $\frac{K^2V}{K+K'}$, and the maximum current $\frac{K}{K+K'}\times\frac{r}{V}$.

Thus it appears that where the capacities of the charged conductors are unequal, contact with the conductor of least capacity will produce the greatest shock, the quantities passing through the body, and currents, being in the inverse proportion of the capacities in the two cases.

This case is perhaps not very practical, as electric supply mains, unless one was an aerial conductor and the other buried, would be, as a rule, equal in capacity. Also, there would be in any length of mains great probability of sufficient leakage to determine the potentials, irrespective of capacity, with continuous currents.

Secondly—Let the conductors A and B be concentric tubes, as in the Ferranti mains, B being outside and entirely enclosing A, except at the two ends, where the conductors are connected to the generator and receiver respectively, or to the generator at one end and the other insulated, which is the simpler case to consider.

In this case there will be no inductive action between the conductors and the earth with the conditions postulated for the generating source, and in the absence of any extraneous charge, and the potential of B with respect to the earth will be zero.

For the quantities on A and B must be equal, and no free charge can be given to B by the source unless it is leaky. If the conductors are transmitting working currents, this condition will be modified by the slope of potential on B, which will then, if insulated, be at zero-potential at the centre of its length.

The same reasoning holds with alternating currents, but in this case the tendency to low potential on the outer conductor is stronger on account of the capacity current.

In fact, with such a length of cable as is used on the Deptford trunk mains—each main having, I am informed by Dr. Fleming, a capacity of about 15 microfarads between the outer conductor and the earth—it would be necessary to have such a considerable leak on the generator or receiver at or near the point of connection to the inner conductor, to raise the potential of the outer much above the earth, that, considering the pressure on the inner conductor, a breakdown must result, and this even if there were no metallic connection to earth on the outer conductor.

It is obvious, too, that no leakage between inner and outer could affect the potential of the latter, except to the extent due to the resulting current and the resistance of the conductor.

The writer pointed out, at the time that the question of the use of an earth connection on these trunk mains was first discussed, that the outer conductor would, even without this connection, always be at a low potential so long as the circuit was in a workable condition; and he has recently been informed that this is found to be the case at Rome.

The earth connections in use have, however, important functions as safeguards in the event of a breakdown in a main transformer.

It is somewhat curious to note that the charge on the outer conductor of the Deptford trunk mains at any instant does not come from the terminal of the dynamo in connection with this conductor, but from that connected to the inner conductor, and passes through the transformer.

Thirdly—Let the capacities of A and B be negligible, but their insulation be no longer perfect, the insulation resistance of A being R, and of B, R'.

Then, with a steady potential difference, the potential of A will be $\frac{RV}{R+R'}$, and of B, $\frac{R'V}{R+R'}$, on the principle of equal emission.

If contact be now made with A, its potential is at once reduced to $\frac{rRV}{rR+R'(R+r)}$,

and that of B increased to $\frac{R'(R+r)V}{rR+R'(R+r)}$;

the current through the body being $\frac{RV}{rR+R'(R+r)}$.

If the conductors have appreciable capacity as well as leakage, there will result in every case a discharge through the body due to the rearrangement of potentials with respect to the earth, since the effect of the contact must be to lower the potential of the conductor touched.

Fourthly—The general case with leakage and capacity with alternating currents.

This requires working out. Let, as before, A and B be the two conductors between which an alternating pressure, maximum V, is maintained at a frequency n; and let them be considered to be separate conductors with negligible mutual electrostatic induction.

Let K be the capacity, R insulation resistance } of A.
K' capacity, R' insulation resistance } of B.
V_a maximum pressure of A from earth;
V_b maximum pressure of B from earth;
$p=2\pi n$.

The current at any instant flowing to each conductor will be compounded of the charging and leakage currents respectively, and the phase angle between the pressure and the current for each conductor will depend upon the capacity and insulation resistance, and will not be the same for the two conductors unless the product of the capacity and insulation resistance is the same for each.

But the current in each conductor must be identical in phase, and equal at any instant, on the principle of continuity.

Therefore, in general, there will be a difference in phase between V_a and V_b, as shown in Fig 1.

Let ϕ be the angle measuring this difference; and, assuming the sine law of variation, we have at any instant the potential $A=V_a\sin\alpha$, and of $B=V_b\sin(\alpha+\phi)$, where α is the phase angle; and as the quantity flowing to each conductor in the succeeding instant is the same,

$$K V_a d(\sin\alpha)+\frac{V_a}{R}\sin\alpha\,dt=$$

$$K' V_b d[\sin(\alpha+\phi)]+\frac{V_b}{R'}\sin(\alpha+\phi)\,dt,$$

$$\text{or } pK V_a\cos\alpha+\frac{V_a}{R}\sin\alpha=pK' V_b\cos(\alpha+\phi)+\frac{V_b}{R'}\sin(\alpha+\phi).$$

Since this equation is true for all values of α, let $\alpha=0$, then

$$pK V_a=pK' V_b\cos\phi+\frac{V_b}{R'}\sin\phi \quad . \quad . \quad . \quad . \quad (1).$$

Again, let $\alpha=\frac{\pi}{2}$,

then $$\frac{V_a}{R}=\frac{V_b}{R'}\cos\phi-pK' V_b\sin\phi \quad . \quad . \quad . \quad (2);$$

whence, $$\tan\phi=\frac{p(KR-K'R')}{1+p^2KK'RR'} \quad . \quad . \quad . \quad . \quad . \quad (3).$$

The straight line joining the extremities of V_a and V_b represents V in phase and magnitude; whence,

$$V_a^2+V_b^2+2V_aV\cos\phi=V^2 \quad . \quad . \quad . \quad . \quad (4).$$

Digitized by Google

From these equations the values of V_a and V_b can be deduced in terms of V; but, as the resulting formulæ are somewhat cumbrous, it is simpler to proceed thus:—First, determine ϕ from equation (3); secondly, determine θ, the angle between V_a and C, the current, from the equation,

$$\tan\theta = \frac{p\,K\,V_a}{\frac{V}{R}} = p\,K\,R.$$

The directions of V_a, V_b, and C are thus determined:—Take C of any convenient length on each side of the origin, and from the ends of C drop perpendiculars on V_a and V_b: the distances between the origin and the feet of these perpendiculars are proportional to $\frac{V_b}{R'}$ and $\frac{V_a}{R}$, and may be taken as V_b and $\frac{R'}{R}\ V_a$. This determines the length of V_a and V. In the example shown in Fig 1, $V_b = \frac{V}{2\cdot9}$; or the current through the leak $= \frac{V}{2{,}900}$, maximum.

Fifthly.*—If the insulation of the two conductors be supposed perfect before contact is made with one of them, the equations are simplified.

Let B be the conductor touched, then in the equations R becomes infinity, and $R' = r'$;

whence,
$$\tan\phi = \frac{1}{p\,K'\,r'},$$

and
$$V_b = \frac{p\,K\,r'\,V}{\sqrt{1+p^2\,r'^2\,(K+K')^2}}.$$

Thus the maximum current through the body is given by the equation,

$$C = \frac{p\,K\,V}{\sqrt{1+p^2r'^2\,(K+K')^2}} \quad . \quad . \quad . \quad . \quad . \quad (5),$$

or, if V be virtual volts, this will be the current in virtual amperes.

Here, again, it appears that the discharge through the body varies directly as the capacity, not of the conductor touched, but of the oppositely charged conductor, as has been shown to be the case with unvarying pressure.

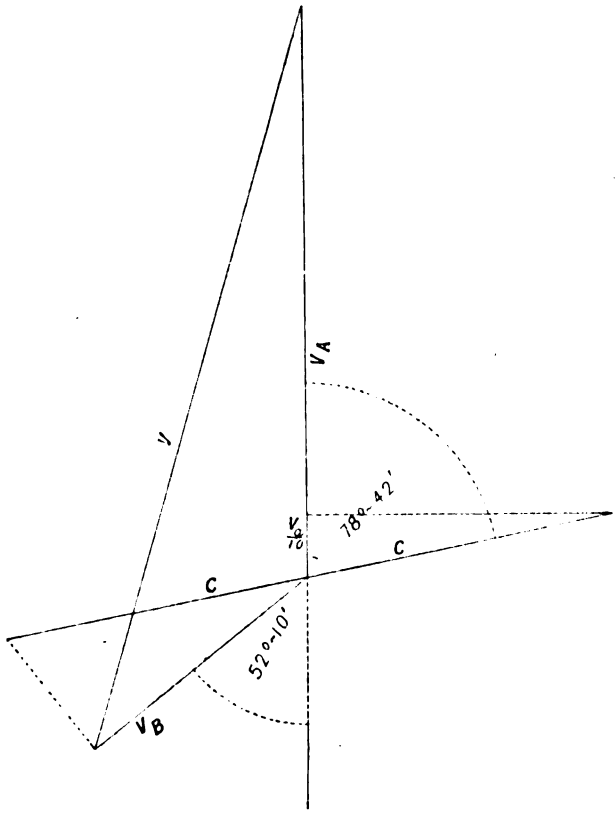

Fig. 1.

* Fig 2 shows the phases and relations of the quantities, V_a in this case being in quadrature with C.

As a rule, with separate conductors, the capacities of each with respect to the earth will be equal, in which case equation (5) is modified to the following:—

$$C = \frac{p\,K\,V}{\sqrt{1+4\,p^2\,r'^2\,K^2}},$$

which may be written, $K = \frac{C}{p\sqrt{V^2 - 4\,C^2\,r'^2}}$,

supposing C, the current through the body, to have the maximum value which may be taken without injury—or, say, 20 milliamperes—r' to be 2,000 ohms, V 2,000 volts, and p to have the value 500, we get from this K about ·02 microfarad only; which clearly shows

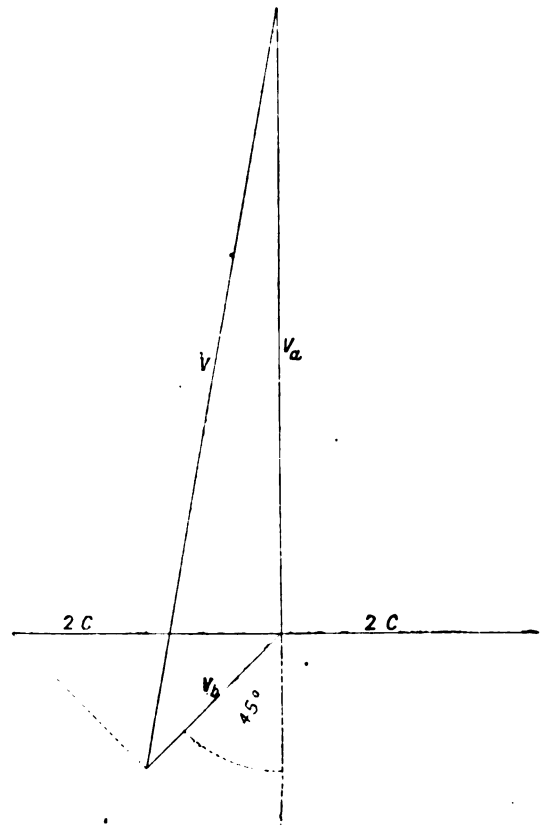

Fig. 2.

the danger of touching bare conductors used for the supply of alternating currents at high pressure, under any conditions.

DISCUSSION (Authorised Abstract).

Dr. FLEMING said the subject treated of was of great practical importance when dealing with pressures exceeding 100 volts. Considerable misapprehension existed on the subject, for it was commonly considered that high pressures were intrinsically dangerous. This, however, was not the case, for, as Mr. Latimer Clark showed years ago, a person could, without injury, receive a shock from hundreds of thousands of volts, provided the quantity of electricity passed through the body was not large. To get a serious shock such as would cause physiological damage it was evident that some appreciable current was necessary. The amount required to produce painful sensations differed greatly, both with different subjects and with the portions of the body through which the current was passed. Some years ago he had tested himself, and found that four or five milliamperes passed through the head produced "swimming in the head," whereas from hand to hand he could tolerate 20 to 30 milliamperes. Some persons might, he thought, be able to take 20 milliamperes through the head. It was not at all unlikely that one-third of an ampere, probably less, passed through any vital organ would prove fatal. Referring to the question as to how the body acts towards the current, whether like a condenser, voltameter, or resistance, he said that the condenser effects were small, but undoubtedly it acted like a voltameter or secondary battery, for it could be polarised, and a current subsequently obtained from it. Measurements of resistance depended greatly on the character and humidity of the skin. At Cambridge, where many experiments were made, it was found that the resistances of boating men from hand to hand were unusually high, and to eliminate more or less the difficulty of obtaining good contact Maxwell suggested that the hands be blistered and connection made by pushing needles through the skin. The experiments were not continued. On the subject of whether a person making a joint in active high-pressure mains, on an insulated chair, he said that if the body acts like a condenser, serious physiological damage might result from a contact under such circumstances, particularly if the current be alternating. The theory that some such condenser action existed was supported by the fact that moderate alternating or fluctuating pressures produced more painful sensations than equal continuous ones. If, however, physiological damage was the result of the electrolysis of some vital tissues, then direct currents would be more likely to prove fatal than alternating currents of the same strength. One interesting fact brought out in Major Cardew's Paper, viz., that the outer conductor of a concentric cable is naturally at zero potential, he had verified

* Cf. "On an Unnoticed Danger in certain Apparatus for Distribution of Electricity," by J. Hopkinson, F.R.S., *Phil. Mag.*, Sept., 1885.

Digitized by Google

experimentally, and he considered it an important point in favour of concentric conductors for high-pressure distribution, and thought the fact ought to be more generally known. In conclusion, he said that quantitative information and data respecting electric shocks, accidental or otherwise, were greatly needed, before the subject could be thoroughly investigated.

Mr. H. NEWMAN LAWRENCE said he had made many experiments on the resistance of persons and on the currents required to produce discomfort, &c. He would not like to have passed the four or five milliamperes mentioned by Dr. Fleming through his own head, and thought it improbable that some persons might withstand 20 milliamperes through that part of the body. The direction of the current with respect to the brain was, however, of great importance. Transverse currents produced most effect, and he found it possible to withstand two or three times as much current when passed longitudinally. Although the passage of such currents might not have very serious consequences immediately, the after results might be serious. In commenting on the difficulty in obtaining reliable information in cases of accidents or other serious shocks, he expressed a hope that the Institution might be able to collect such statistics as completely as possible. Generally, he said, the conditions as to area of contact, condition of skin, earth connection, &c., were not at all clear, and no idea could be gathered from ordinary information as to the actual current passed. He agreed with Dr. Fleming that it was the quantity passed through the body that was the important factor. To know the pressure was not essential, and the ordinary statements that persons received shocks from a certain number of volts were generally misleading.

Mr. ADDENBROOKE remarked that in connection with the Grosvenor Gallery installation he had experienced shocks, and once made an overhead joint on a 2,500-volt circuit with the pressure on. To do this he had a strong teak bracket fixed to the posts, and all the wood and metal work near was covered with india-rubber sheeting. Special tools with insulating handles were used, and a dry day chosen. When he touched the conductor faint blue sparks passed, but nothing to produce discomfort. On another occasion he unconsciously put his hand across a high-pressure switch, and, although he had no recollection of experiencing any shock, he was thrown down. Several men he knew had received serious shocks from a 2,500 volt circuit. In one case, a man was putting up a transformer, and, clinging to an iron bracket that had been recently cemented into a wall, with one hand, he reached up to one of the primary conductors with the other. The pressure was on, and the man was fixed in that position until he was pulled down by his comrades. His hands were severely burnt and he received a severe shock to the system. In another case, when rearranging a customer's service lines, an arc started through a crack in the insulation, to the hand of a man who was holding the wire. He was fixed to the post for some time before being released. The hand was badly burnt, and looked as if a red-hot poker had been laid on for some time. He (Mr. Addenbrooke) believed that the arc was started by perspiration from the man's hand penetrating the crack and making connection through his body to the post. So far as he knew, his constitution was not permanently affected by the shock.

Mr. MORDEY remarked that at the Brush Works they had made high-pressure electrical machinery for the last ten years, and although their testing arrangements were of a temporary kind, and much unskilled labour was employed, they had never had a serious accident due to electrical machinery. Only one instance had occurred in which a man was made insensible. This was a lamp trimmer, who, in taking down a lamp, completed the circuit of a No. 8 Brush machine through his body. A bright arc was seen to pass between the lamp and his hand. He fell from the ladder, and had received a severe burn and shock; but, although a large current must have passed, he suffered no permanent injury to the system. He himself once disconnected the circuit of a No. 7 machine, and held the wires, one in each hand, thus completing the circuit. At the time he was conscious of having an idea that the brushes of the machine needed shifting, to reduce the great sparking that occurred; but he did not know what he had done until after he was released by stopping the machine. Referring to Dr. Fleming's remarks about making joints in high-pressure mains by means of insulated chairs, he said there was no difficulty whatever in doing so. The average person had not sufficient capacity to obtain a dangerous shock. At the Brush Works they constantly handled high-pressure wires with bare hands, and rarely found it necessary to take any precaution, unless the pressure exceeded 2,000 volts. Then they merely stood on india-rubber mats. A packer once in their employ was particularly insensitive to fairly large pressures, for he commonly took hold of the terminals of machines giving about 800 volts. His experience with concentric cables confirmed the statements made by Major Cardew and Dr. Fleming, viz., that the outer conductor was at zero potential. In considering the shocks obtainable from a given source, he said the internal resistance of the source was of great importance; and, as an instance, adduced the fact that vacuum tubes, although requiring induction coils giving sparks corresponding to many thousands of volts to work them, were blown to pieces when put on a 1,000-volt alternator.

Mr. H. HUMAN asked Dr. Fleming, that as he considered danger more a question of current than of pressure, whether he would prefer to take hold of the primary terminals of a transformer rather than those of the secondary.

Prof. AYRTON pointed out that the fact of the outside of a concentric cable being at zero potential depended on the outside being near earth. It would not necessarily be so if it was far removed from other conductors.

Prof. PERRY inquired whether the whole concentric system and generator, if insulated, might not be charged to (say) a million volts above the earth potential.

Major CARDEW, in reply to Prof. Perry, said this could only be done by means of an external source, and in his calculations he had postulated the absence of such sources. There was, he said, no doubt that considerable polarisation could be produced in the human body, for he found that its resistance to steady currents goes down as the pressure increases, and tends to a value which is approximately the same as that found by measurements with alternating currents. For small pressures, however, the effects produced by alternating or fluctuating pressures were much greater than with steady ones. He called Mr. Addenbrooke's attention to a fact pointed out in his Paper, viz., that touching a conductor of a (say) 2,500 volt system did not necessarily imply that a shock corresponding to that pressure was experienced, for the act of contact, in reducing the resistance to earth, would probably lower the difference of potential to about one-third of the stated value.

ON SOME EFFECTS OF ALTERNATING-CURRENT FLOW IN CIRCUITS HAVING CAPACITY AND SELF-INDUCTION.*

BY DR. J. A. FLEMING.

The full analytical treatment of the problem of the propagation of an electric current through a conductor possessing capacity and resistance is one which is by no means simple. If to this is added the consideration of the additional condition that both the line and the receiving and transmitting instruments possess self-induction, the problem in its full generality is a very complex one. For certain assumptions as to the mode of variation of the impressed electro-motive force, and with other limitations, it may be said to have been solved for periodic currents; but, if we consider the practical case of receiving and transmitting appliances of variable inductance, it can hardly be said that analysis enables the results of definite arrangements to be completely predicted. Fortunately, in much practical work the additional complications which arise from the simultaneous presence of capacity and self-induction in the system are negligible, but useful, and existing work is not entirely thus limited; and electrical distribution by means of transformers, alternating currents, and concentric cables forces us to regard phenomena due to the co-existence of inductance resistance and capacity in one circuit, which need interpretation, even if only so far as to enable constructive mistakes to be avoided. We have

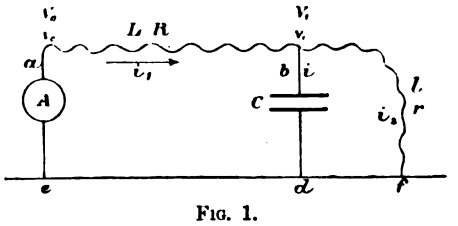

FIG. 1.

already been made aware by experience that under these circumstances unexpected effects often make their appearance, and these demand examination at this period in the history of the large-scale manufacture and distribution of electric current, to enable us to appreciate the meaning of observed facts. The object of the present Paper is to gather together some of the results already arrived at, and to point out a part of the existing state of knowledge of the propagation of alternating currents in circuits in which neither the inductance nor the capacity are so small that they can be left unconsidered in their effects.

2. It will be convenient to start the inquiry by examining a typical and simple case involving simple periodic electromotive force, and inductance and capacity in the circuit. Such problems have already been treated analytically by Dr. Hopkinson; geometrically by Mr. Blakesley, Major Cardew, Mr. Kapp, myself, and others.†

Let A be an alternator feeding an inductive circuit, $a\,b\,f$, of which the section $a\,b$ has inductance L and resistance R, and the section $b\,f$ has inductance l and resistance r. At b let a condenser of capacity C be inserted, and let the terminals e, d, and f of the line condenser and alternator be to earth.

Let v_0 be the potential at a at any instant, and v_1 that at b; and let V_0, V_1, be the maximum values of these potentials, supposed to vary harmonically. Let i_1 and i_2 be the currents at any instant in the sections of the line $a\,b$, $b\,f$, and i the current flowing into the condenser, and I_1, I_2, I, the maximum of the same. Under these circumstances we proceed to investigate what are the relative values of V_0 and V_1, or their ratio to one another. We have always,

$$i_1 = i + i_2. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1);$$

* Paper read May 7, 1891, before the Institution of Electrical Engineers.

† Dr. Hopkinson's Paper on "The Theory of Alternating Currents" is in the *Proceedings* of the Institution of Electrical Engineers (late *Journal* of the Society of Telegraph Engineers) for 1884, Vol. XIII., p. 496. Mr. Blakesley's Papers are collected in his admirable little book on "Alternating Currents."

Digitized by Google

also, $$i = C\frac{d v_1}{d t} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2),$$

and $$l\frac{d i_2}{d t} + r i_2 = v_1 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3),$$

but we may write, as the currents are simply periodic,

$$i_1 = I_1 \sin p t \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4),$$

where $p = 2\pi n$, n being the frequency of the periodic current in $a\,b$, and t the time reckoned from the instant when the current in this first section is zero.

By elimination of v_1, i_1, and i from the above four equations we find easily that

$$C l\frac{d^2 i_2}{d t^2} + C r\frac{d i_2}{d t} + i_2 = I_1 \sin p t \quad . \quad . \quad . \quad . \quad (5).$$

Since i_2 must also be a simple periodic current, lagging in phase behind that of the current i_1, we may take i_2 to be of the form,

$$i_2 = I_2 \sin (p t - \theta) \quad . \quad . \quad . \quad . \quad . \quad . \quad (6).$$

Hence, by differentiation of (6), and substitution in (5), we arrive at

$$(1 - C L p^2) I_2 \sin (p t - \theta) + C r p^2 I_2 \cos (p t - \theta) = I_1 \sin p t. \quad 7),$$

which, by a well-known transformation, may be put in the form

$$I_2 \sqrt{(1 - C l p^2)^2 + C^2 r^2 p^2} \sin (p t - \theta + \phi) = I_1 \sin p t \quad . \quad (8).$$

Both sides of this equation (8) are expressions for the same thing —namely, the value of i_1—hence, equating coefficients, we have

$$\left(\frac{I_1}{I^2}\right)^2 = (1 - C l p^2)^2 + C^2 r^2 p^2. \quad . \quad . \quad . \quad (9).$$

Putting $a = 1 - C l p^2$, and $b = C r p$, we have,

$$\left(\frac{I_1}{I_2}\right)^2 = a^2 + b^2 \quad . \quad . \quad . \quad . \quad (10).$$

This gives us the ratio of the maximum, or square root of the mean square values, of the currents in the two sections of the line on either side of the condenser.

It is convenient next to shift the origin of the time, and take the instant when the current i_2 is zero as a point from which to reckon the time.

Doing this, we can write,

$$i_2 = I_2 \sin p t \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (11);$$

and, accordingly, from (10),

$$i_1 = I_2 \sqrt{a^2 + b^2} \sin (p t + \theta);$$

or $$i_1 = I_2 (a \sin p t + b \cos p t) \quad . \quad . \quad . \quad . \quad (12);$$

hence, $$i_1 - i_2 = I_2 (\overline{a - 1} \sin p t + b \cos p t) \quad . \quad . \quad (13),$$

but from (1) and (2)

$$i_1 - i_2 = C\frac{d v_1}{d t};$$

$$\therefore C\frac{d v_1}{d t} = I_2 (\overline{a - 1} \sin p t + b \cos p t);$$

or $$v_1 = \frac{I_2}{C p} (b \sin p t + \overline{1 - a} \cos p t) \quad . \quad . \quad . \quad (14);$$

$$\therefore V_1 \frac{I_2}{C p} \sqrt{\overline{a - 1}^2 + b^2} = I_2 \sqrt{r_2 + p_2 l_2} \quad . \quad . \quad (15).$$

We have next to find the value of V_0.

$$v_0 - v_1 = L\frac{d i_1}{d t} + R i_1 \quad . \quad . \quad . \quad . \quad (16),$$

and if we substitute in (16) the value of i_1 given in (12), and of v_1 given in (14), and integrate, we arrive at

$$v_0 = I_2 \left\{ \left(R a + \frac{b}{C p} - L p b \right) \sin p t + \left(R b + \frac{1 - a}{C p} + L p a \right) \cos p t \right\};$$

but, since $\frac{b}{C p} = r$, and $\frac{1 - a}{C p} = p l$, we get by proper substitution in the above equation, and by the application of the rule for harmonic maxima, the equation,

$$V_0 = \frac{I_2}{C p} \sqrt{(A^2 + B^2)(a^2 + b^2) + 2 B b - 2 A a + 1} \quad . \quad . \quad (17),$$

where

$$A = 1 - C L p^2; \qquad a = 1 - C l p^2;$$
$$B = C R p; \qquad b = C r p.$$

Equations (15) and (17) give us the values of the maximum or mean potentials at the generator and condenser end of the line $a\,b$. If we divide equation (17) by equation (15), we get a value for the ratio of V_0 to V_1. A little tedious process of division and substitution brings us finally to the required result, which is,

$$\frac{V_0}{V_1} = \sqrt{(A^2 + B^2) + (1 - C p^2)\frac{R^2 + p^2 L^2}{r^2 + p^2 l^2} + \frac{2 L l p^2}{r^2 + p^2 l^2} + \frac{2 R r}{r^2 + p^2 l^2}} \quad (18).$$

This last equation furnishes us with the required result, viz., the ratio of the maximum or mean potentials at the ends of the inductive line $a\,b$ in terms of the coefficients of inductance, capacity, and resistance.

Given V_0. it enables us to calculate V_1, and to say whether V_1 is greater than, less than, or equal to V_0.

3. Let us examine some particular cases. Suppose $r^2 + p^2 l^2 = x$ — that is, suppose the section of the line beyond the condenser removed—then

$$\frac{V_0}{V_1} = \sqrt{A^2 + B^2} = \sqrt{(1 - C L p^2)^2 + C^2 R^2 p^2} \quad . \quad . \quad (19).$$

This reduced case was treated by Dr. Hopkinson long ago,* and he showed, as we can easily see, that it is possible for the ratio of V_0 to V_1 to be *less* than unity—that is, for the potential at the receiving end, or at the condenser, to be *greater* than the potential at the sending end.

It is very easy to state the conditions under which this is the case. In order that V_1 shall be greater than V_0, or that there may be a rise of pressure, we must have

$$\sqrt{(1 - C L p^2)^2 + C^2 R^2 p^2}$$

less than unity ; hence we must have

$$(1 - C L p^2)^2 + C^2 R^2 p^2 < 1,$$

or $$1 + C^2 L^2 p^4 - 2 C L p^2 < 1 - C^2 R^2 p^2,$$

or $$C < \frac{2 L}{R^2 + p^2 L^2} \quad . \quad . \quad . \quad . \quad . \quad (20).$$

If L, R, and p are constant, the value of C which makes the ratio of V_1 to V_0 a maximum is

$$C = \frac{L}{R^2 + p^2 L^2}$$

Hence, if the capacity, C, of the condenser, measured in farads, is *less than* the quotient obtained by dividing twice the inductance of the line L, measured in henrys, by the square of the impedance ($R^2 + p^2 L^2$), we shall, under these circumstances, find a rise in pressure at the condenser end. For example, suppose the value of n or the frequency is 67, then $p = 421$, and $p^2 = 177{,}241$. If R = 1 ohm, and L = ·1 henry, then $R^2 + p^2 L^2 = 1{,}773$, and there ought to be a rise in pressure if C is greater than 112 microfarads ; or, if R = 1 ohm, and L = 100 henrys, then $R^2 + p^2 L^2 = 1{,}772{,}410{,}000$, and there ought to be a rise in pressure if C is greater than one-eighth of a microfarad. Generally speaking, the greater L, the less will be the critical value of C. For high frequencies the criterion of rise of pressure at the condenser end is

$$C < \frac{2}{L p^2}.$$

That is to say, the critical capacity is just twice that which will at the given periodicity nullify the inductance of the armature circuit. It is worth while to note that even if the criterion for rise of pressure at the condenser end is fulfilled by L, R, C, and p, yet, as seen from equation (18), a sufficiently small impedance ($\sqrt{r^2 + p^2 l^2}$) in the shunt may nullify the effect and force V_1 to be less than V_0.

4. These *condenser effects*, as they may be called, are very strikingly shown when currents of high frequency are used. Quite recently, Mr. Nikola Tesla has published some interesting observations and experiments on alternating currents with the very high frequencies of 10,000 to 20,000 alternations per second,† and amongst these he has described an experiment with a condenser joined across the poles of such an alternator. A machine was used giving about 20,000 alternations per second. Two bare wires about 20 feet in length were attached to the poles, and their ends connected to the terminals of a condenser. The difference of potential between parallel points on these wires was explored by a voltmeter, and it was found that the potential difference of parallel points on the wires steadily rose inch by inch from 65 volts at the terminals of the alternator to 120 volts at the terminals of the condenser ; and the writer states that observations on the self-induction of the armature in its position of maximum and minimum inductance showed that the capacity which gave the greatest rise at the condenser end corresponded apparently to that which would about nullify the mean self-induction calculated from the observed maximum and minimum. This entirely corresponds to the above theoretical deduction.

5. The fact that when a condenser is thus charged by an alternating-current machine its terminal potential difference may be very much greater than that of the machine terminals, appears to have been noticed experimentally prior to the time when the simplest case was mathematically treated by Dr. Hopkinson. In the paper of the latter, above referred to, it is mentioned that Dr. Muirhead had observed it experimentally. In the discussion which

* See *Proceedings* of the Institution of Electrical Engineers for 1884, page 513.

† See *The Electrician*, March 6 1891, p. 549.

Digitized by Google

followed Dr. Hopkinson's paper, Mr. Blakesley dealt with the same matter in some geometrical diagrams, and Prof. Ayrton mentioned that in 1878 or 1879 Mr. Munro took out a patent for the use of condensers in combination with an alternating-current machine. In any case, the experimental verification of a rise of pressure along the line leading from the machine to the condenser is complete.

6. In his book on "Alternating Currents," p. 55 (2nd edition), Mr. Blakesley has treated by his geometrical methods the case examined above, with the object of showing that the employment of a condenser in this manner in combination with a pair of inductive circuits may, under certain conditions, cause the current in the remote, or shunt, circuit to be greater than the current in the circuit in connection with the machine; and he shows there that a similar criterion to the one given above applies also to the relative current-strengths in the two sections—viz., that the current I_2 in section $b\,f$ will be greater than the current I_1 in section $a\,b$ if C is less than $\frac{2\,l}{r^2+p^2\,l^2}$.

Hence, generally, we have that the maximum or mean potential V_1 at the terminals of the condenser will be less than, equal to, or greater than the maximum or mean potential at the terminals of the machine V_0, according as the capacity, C, of the condenser is greater than, equal to, or less than the quantity, $\frac{2\,L}{R^2+p^2\,L^2}$, in numerical value; and also that the maximum or average current-strength in the remote, or shunt, section of the line will be less than, equal to, or greater than the maximum or mean current-strength in the section of the line near to the machine, according as the capacity, C, of the condenser is greater than, equal to, or less than the quantity, $\frac{2\,l}{r^2+p^2\,l^2}$, in numerical value.

Note that if R is measured in ohms and L in henrys, C must be measured in farads.

If we look again at the equation,

$$\left(\frac{V_0}{V_1}\right)^2=(1-C\,L\,p^2)+C^2\,R^2\,p^2,$$

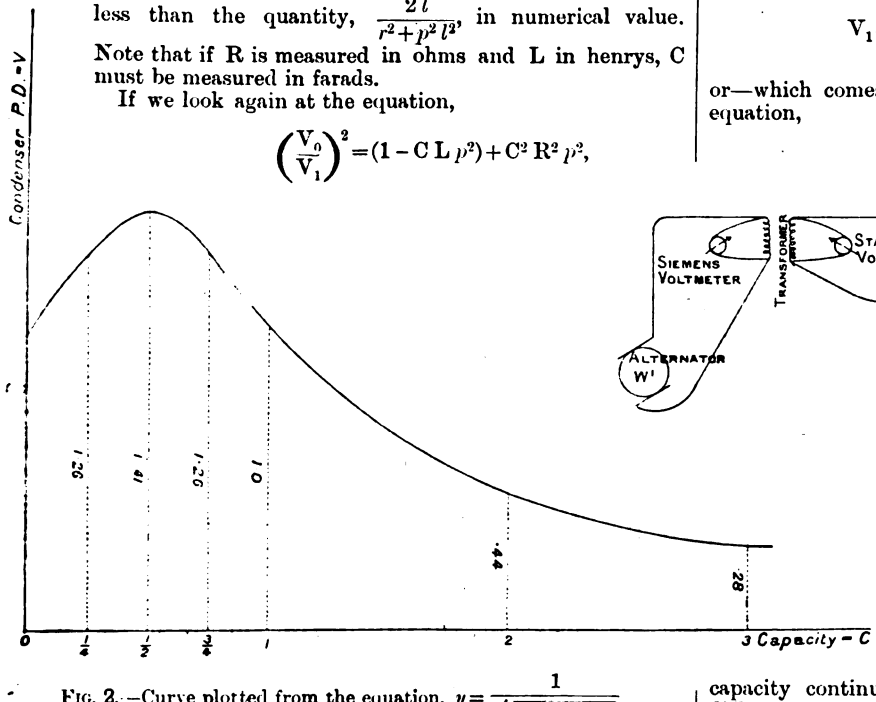

FIG. 2.—Curve plotted from the equation, $y=\frac{1}{\sqrt{(1-X)^2+X^2}}$

or $$V_1=\frac{V_0}{\sqrt{(1-C\,L\,p^2)^2+C^2\,R^2\,p^2}}.$$

and note what are the conditions under which V_1 will be *greater* than V_0, or the pressure at the condenser end greater than the pressure at the machine end of the line, we see that it depends upon whether the right-hand expression, when worked out numerically, is a proper fraction. Since almost any capacity which occurs in practice is numerically represented by a very small fraction when the farad is the unit, if p^2 is not very great $C^2\,R^2\,p$ will nearly always in practice be a proper fraction when we insert values of C and R in farads and ohms. Hence the condition of rise of pressure will depend almost always on whether $C\,L\,p^2$ is numerically greater than 2 when C and L are measured in farads and henrys; and if C is very small, either L or p must be very large to secure this result, and *vice versâ*. Hence, generally, if the inductance of the machine circuit is very large, a comparatively small capacity across its poles may give rise to a very great condenser effect; but if the inductance of the machine is small, a very large capacity will be needed to bring about the increased pressure at the terminals of the condenser.

Suppose, for instance, that a transformer is used to raise the pressure of an alternator, and that across the high-pressure terminals of the transformer is placed a condenser of capacity C, this may be either a condenser of the ordinary form, or a certain length of concentric cable insulated at the far end and having a definite capacity. Let us suppose that the high-pressure circuit of the transformer has a great many turns of wire. The mean inductance of this high-pressure coil is then the L in our formula, its resistance is our R, and p^2 is $4\,\pi^2 n^2$, where n is the frequency of the alternator. To fix our ideas, let $n=83=10{,}000$ alternations per minute, then $p^2=273{,}947$.

Let R = 10 ohms, and L = 200 henrys—values possible to be reached in practice—then, if C is measured in microfarads, we see that that $(1-C\,L\,p^2)^2+C^2\,R^2\,p^2$ becomes

$$\left(1-\frac{C\times 273{,}947\times 200}{10^6}\right)^2+\frac{C^2\,27{,}394{,}700}{10^{12}}=(1-55\,C)^2+\cdot 00003\,C,$$

nearly.

If C is absolutely zero, the value of this quantity is unity. If C is equal to 1-27th of a microfarad, this quantity is also, roughly, equal to unity. If C has any value between zero and 1-27th of a microfarad—say 1-50th of a microfarad—then, since $\left(1-\frac{55}{50}\right)^2+\cdot 00003\,\frac{1}{50}=\cdot 01$, nearly, we see that the ratio of V_0^2 to V_1^2 will be 1 to 100, or V_1 will be ten times V_0. Hence it is obvious there is a narrow range of capacity within which the pressure at the condenser terminals may be enormously increased over that at the machine terminals; but if the capacity is altered so as to take it outside these critical limits, the so-called resonance effects will vanish.

The best way to see how the value of V_1, or the condenser potential, varies with variation of the capacity, other quantities being constant, is to plot the equation,

$$V_1=\frac{V_0}{\sqrt{(1-C\,L\,p^2)^2+C^2\,R^2\,p^2}}$$

or—which comes to the same thing, and is simpler to plot—the equation,

$$y=\frac{1}{\sqrt{(1-x^2+x^2}}.$$

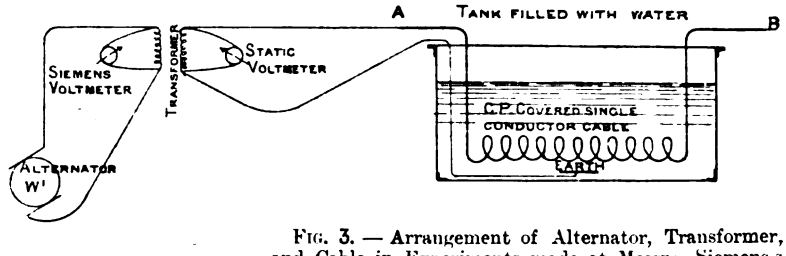

FIG. 3. — Arrangement of Alternator, Transformer, and Cable in Experiments made at Messrs. Siemens's Works.

This has been done in Fig. 2, and a curve representing the variation of V_1 in terms of C, or of the condenser plate potential difference in terms of its capacity, supposed variable, is there drawn, on the assumption that V_0, L, R, and p^2 have certain constant values. We see that the curve ordinate has a maximum corresponding to a certain capacity, and that beyond that point increase in capacity continuously diminishes the condenser plate potential difference.

The condenser effect will be at a maximum when C and L have such magnitudes that $C\,L\,p^2$ is unity, and C has at the same time a small value. In this case V_1 may be hundreds or thousands of times greater than V_0. In testing condensers with alternating-current machines, it is very important not to have that particular critical relation between C, p, and L, or the capacity, frequency, and inductance of the machine, which will bring about the resonance effect, or else the testing process may be a destructive process as far as the condenser is concerned.

8. Quite similarly, we can show that if the capacity of the condenser is fixed, there is a certain range of inductance of the circuit of the alternator within which the resonance effect takes place. For example, let C = ·1 microfarad, as before, $p^2=273{,}947$, and R = 10 ohms, then for the ratio of V_0^2 to V_1^2 we have the value

$$\left(1-\frac{273{,}947\,L}{10^7}\right)^2+\frac{273{,}947\times 100}{10^8}=(1-\cdot 027\,L)^2+\cdot 27.$$

If L = 0, this ratio is greater than unity; if L = 74, the ratio is again greater than unity; but for values of L between 0 and 74, the ratio is less than unity. In other words, within these limits of the inductance the pressure at the poles of the condenser is raised.

The above theory is shown to be confirmed in its general character by the results of some highly interesting experiments, made more

than a year ago (April 10, 1890) at the works of Messrs. Siemens Bros., which Mr. Alexander Siemens has sent to me. A Siemens W_1 alternator

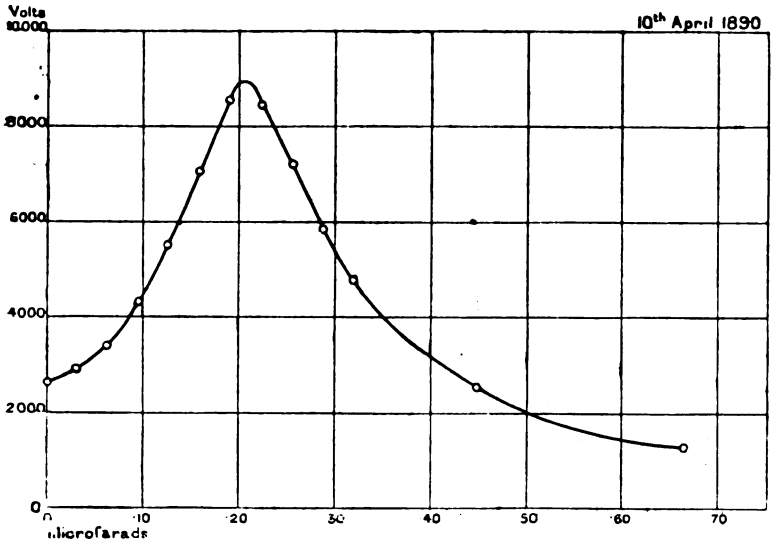

FIG. 4.—Curves showing Variation in Voltage in Secondary (high voltage) Circuit by Varying Capacity in Secondary (high voltage) Circuit. The experiments have been made with No. 2 transformer, and current was obtained from W′ machine, frequency being 100 ∿. The exciting current was constant, and the alternator was running at 750 revolutions during all the experiments.

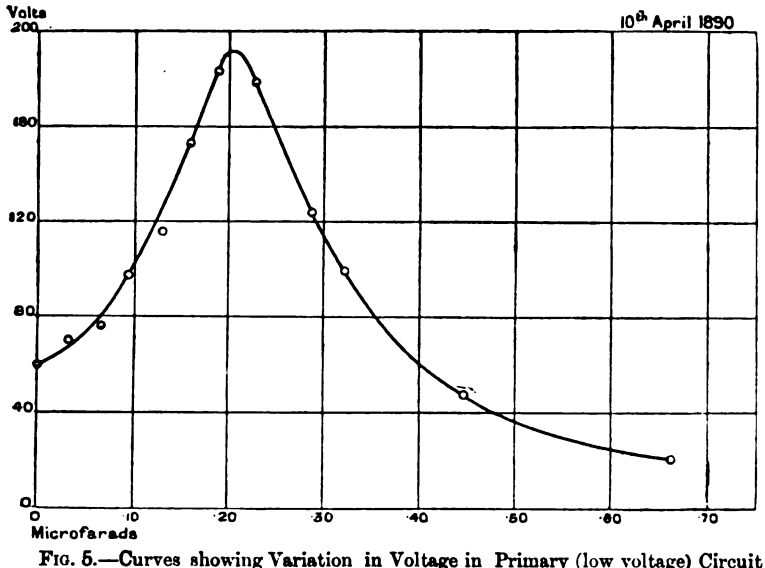

FIG. 5.—Curves showing Variation in Voltage in Primary (low voltage) Circuit by Varying Capacity in Secondary (high voltage) Circuit. The experiments have been made with No. 2 transformer, and current was obtained from W′ machine, frequency being 100 ∿. The exciting current was constant, and the alternator was running at 750 revolutions during all the experiments.

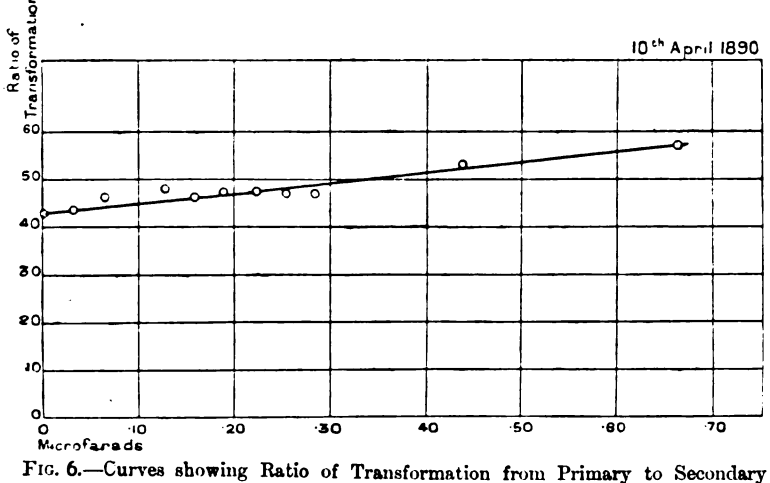

FIG. 6.—Curves showing Ratio of Transformation from Primary to Secondary Circuit resulting from Figs. 1 and 2.

was kept running at a constant speed of 750 revolutions, and the exciting current was also kept constant. The current from this was sent into the thick-wire coil of a No. 2 transformer. The terminals of the fine-wire circuit were connected to various lengths of single-conductor cable, having gutta-percha insulation and immersed in a tank; the cables being insulated at the far ends, and forming thus a condenser attached to the secondary of the transformer (see Fig. 3). The pressure was measured at the terminals of the machine, and at the terminals of the transformer on the secondary, or condenser side. The experiments consisted in varying the length of the cable used so as to vary the capacity, and in observing the pressure at the two sides of the transformer whilst the dynamo was kept running at constant speed and excitation. The results are embodied in the following series of interesting curves. The horizontal distances in the diagrams represent the various capacities of the open-circuit cables or condenser attached to the terminals of the secondary of the transformer. The vertical ordinates in Fig. 4 represent the observed potential difference of the two surfaces of this condenser—that is, the potential difference at the secondary terminals of the transformer.

It will be seen from Fig. 4 that when the capacity is zero this potential difference was 2,500 volts. As the length of cable was increased continuously, this potential difference rose up to 8,500 volts, corresponding to a capacity of ·2 microfarad, and then fell again to 2,500 volts, at a capacity of ·45 microfarad. Hence, corresponding to a certain capacity—viz., ·2 microfarad—the pressure is multiplied about 3½ times, and there is a certain narrow range of capacity over which this exaltation of pressure takes place. At and beyond ·45 microfarad capacity, the presence of the condenser reduces the normal pressure continuously. The pressure on the primary side of the transformer is also increased, as shown in the curve given in Fig. 5, which represents a series of similar pressure observations taken on the primary side of the transformer. It will be seen that the same general effect takes place on the primary side. It will be seen how entirely these curves deduced from observation agree with the theory as illustrated by the curve in Fig. 2. The curves in Figs. 4 and 5 are generally similar, but, if superimposed, will be found to be not quite so. If the ratio of corresponding ordinates is set off so as to form a fresh curve (Fig. 6), this curve will give the variation of change ratio of the transformer corresponding to the various capacities, and we see that this change ratio is altered progressively from 1 : 43 to 1 : 57, as the capacity of the condenser on the secondary is changed from zero to ·65 microfarad. It is evident, therefore, that in applying transformers to test cable, such as concentric cable, which possesses sensible capacity, we must be on our guard against this alteration of the change ratio of the transformer, or else we may be misled as to the real pressure being applied to the cable.

(To be continued.)

THE ELECTRIC TRANSMISSION OF POWER AT HIGH-PRESSURE.

In a letter to the *Elektrotechnische Zeitschrift* several criticisms were recently made by Herr Aug. Schneller, with regard to the Oerlikon transmission of power experiments.* Let us examine, he says, the losses which are likely to occur on *the actual line* between Lauffen and Frankfort. The power in the primary circuit is to be about 186,000 watts, say 30,000 volts and 6·2 amperes. In a copper wire 5 mm. in diameter and 350 kilometres long, the fall of pressure will amount to 1,830 volts or 6·1 per cent. If we suppose the conductor to be an aërial one, supported at every 50 metres, we shall have 3,500 posts and 7,000 insulators. A good oil insulator will offer a resistance of 1,000 megohms to a low-pressure. With 7,000 insulators, we have, therefore, an insulation resistance of 150,000 ohms, allowing a leakage current of ·2 ampere, or 3·2 per cent. But, according to Herr Schneller, at 15,000 volts the loss through a well-dried insulator amounts to 2·3 watts, to 4·7 watts at 20,000 volts, and to 15 watts at 30,000 volts, which gives a total loss of 100,000 watts on the Frankfort line, without taking into account fog or rain. The possible leakage between the conductors themselves Herr Schneller thinks may amount to ·15 watt per metre, or 26,000 watts in all. Taking these factors Herr Schneller comes to the conclusion that only 37 H.P. will be available at Frankfort. But this is not all. Taking the striking dis-

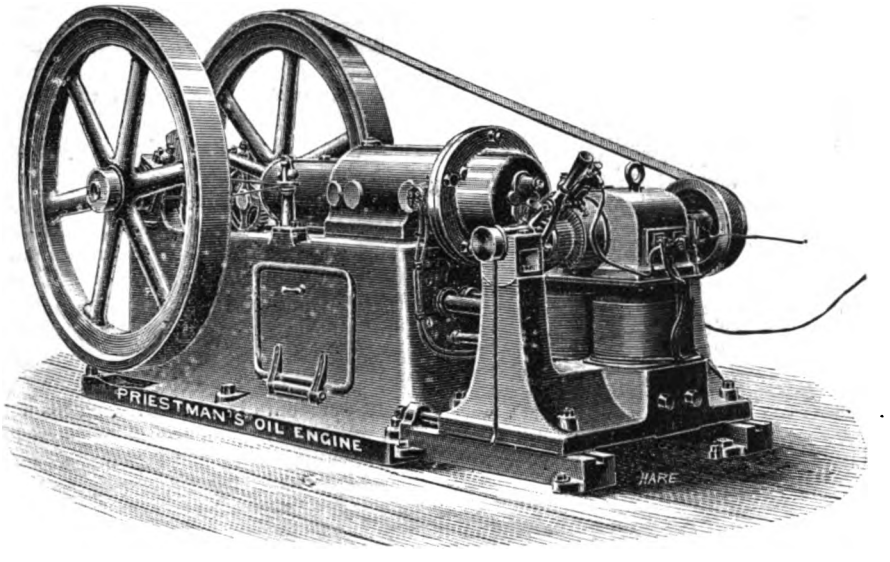
* See *The Electrician*, Vol. XXVI., March 27, 1891, p. 637.

Digitized by Google

tance of 20,000 volts to be 26mm., and with a condenser of 15mm. to be 80mm., Herr Schneller is of opinion that with the 6,000 square metres presented by the line the striking distance will become something considerable.

Without following the author to this pessimistic conclusion, it may be safely said that the electric transmission by an overhead line of 300 H.P., at a pressure of 30,000 volts, and to a distance of over 100 miles, will not be without unexpected developments.

ELECTRIC LIGHTING BY PRIESTMAN OIL ENGINE.



Messrs. Priestman Bros. (Limited), of Hull, and 73A, Queen Victoria-street, London, E.C., have recently supplied to Mr. G. Aspland, of Boston, one of their 3 H.P. oil engines and Taunton dynamo, the latter made by Mr. F. M. Newton, of Taunton. The engine and dynamo are mounted upon a bogie, fitted with road wheels. The dynamo is driven direct from the flywheel of the engine at a speed of 1,300 revolutions, and supplies four arc lamps, with a current of six amperes, each at a pressure of 60 volts. All the wire leads to the lamps are attached to main cables by means of special brass clips, which can be detached at a moment's notice.

Messrs. Priestman Bros. (Limited) are now making oil engines from 1 H.P. to 25 H.P. A large number of engines have been supplied for electric lighting, orders having recently been executed, amongst others, for this purpose, for the Victorian and New South Wales Governments.

THE ANGLO-AMERICAN TELEGRAPH COMPANY AND THE PARIS-NEW YORK TELEGRAPH COMPANY.

The following is an account of the action between the Anglo-American Telegraph Company and the Paris and New York Telegraph Company, which was argued before the French Council of State in Paris, on Friday, the 1st inst. :—

The Council of State in Paris was occupied, on Friday last, with hearing the appeal of the Anglo-American Company from the adverse decision of the Council of Prefecture of the Seine on March 19, 1889, in the action of that Company against the Paris and New York Telegraph (P.Q.) Company. This action was first commenced in the Tribunal of Commerce of Paris early in 1887 for specific performance by the Paris and New York Company of the joint purse agreements made by them, in 1880 and 1882, with the Anglo-American, the Direct United States Cable, and the Western Union Companies, or, in the alternative, for damages for breach of those agreements.

After the agreement of 1880 had been in operation for six years, greatly to the advantage of the Paris and New York Company, the Mackay-Bennett combination (Commercial Cable Company) appeared to have obtained a preponderating influence on the French Company, and on December 31, 1886, the Managing Director of that Company abruptly gave notice to the Anglo-American and other Companies, parties to the agreements, that, in pursuance of a letter of the previous day from M. Granet, then Minister of Posts and Telegraphs, the Paris and New York Company put an end to the joint-purse agreements as being contrary to the terms of their concession from the French Government, which required the written consent of the Government to any such agreement, and which consent the Government had not given.

Count Dillon was then Managing Director of the Commercial Cable Company, and had previously held the same position in the Paris and New York Company, and it was alleged that the Minister's letter had been written at the instigation of one of those companies. It is certain that the French Company took no step to modify the Minister's requisition, or to obtain from him the written consent which was said to be necessary, and that on January 27, 1887, they made an agreement with the Commercial Cable Company.

On January 9, 1888, the Tribunal of Commerce gave judgment in the action in favour of the Anglo-American Company, requiring the Paris and New York Company to resume performance of the agreements, and awarding the Anglo-American Company heavy damages. The Paris and New York Company appealed to the Court of Appeal, and there for the first time objected to the jurisdiction of the Tribunal of Commerce, on the ground that, as the question arose under a Government concession, the interpretation of that concession, and of the Minister's letter, belonged to the administrative tribunals (the Council of the Prefecture of the Seine, with appeal to the Council of State). The Court of Appeal so far agreed in this view as to direct that the questions on the meaning and effect of the concession and of the Ministerial letter should be referred to the administrative tribunals, and reserved its own decision on the other matters in issue.

On March 19, 1889, the Council of the Prefecture decided in favour of the Paris and New York Company's contentions. From this decision the Anglo-American Company appealed to the Council of State. The case was argued at length on Friday, and the legal commissary of the Government having given his opinion on several grounds against the Paris and New York Company, the President of the Council, at 10 o'clock on the same night, pronounced judgment in favour of the Anglo-American Company, basing the decision of the Council on the ground that the Ministerial letter of December 30, 1886, was not an order to denounce or annul the agreements, but simply a notice to the Paris and New York Company to observe the conditions of their concession, and that this letter was no obstacle to their taking the necessary steps to obtain the express written consent of the Government to the agreements. The defendants were condemned to pay the costs.

This important judgment, although final on the main legal point, is not an end of the litigation. The case will now go back to the Court of Appeal to deal with the other matters, including the amount of damages to be paid by the defendants, which, at the date of the judgment of the Tribunal of Commerce, amounted to about £32,000. The damages payable after the notification of the first judgment were reserved by the Tribunal of Commerce for further consideration, and will now have to be fixed.

With respect to the written consent of the Government not having been originally obtained, it is explained that, in October, 1880, the late M. Pouyer-Quertier applied to M. Cochery, then Minister of Posts and Telegraphs, for his consent to the first agreement, and was informed by M. Cochery that the agreement, not being for an amalgamation or lease of the lines, did not require the consent of the Government. In consequence of this statement the agreement was put in force and acted upon for six years, with the results above stated.

LEGAL INTELLIGENCE.

In Re the Electrical Engineering Corporation (Limited).

Upon the hearing of this petition, before Mr. Justice Kekewich, last Saturday, a question of importance arose in reference to the effect of the new procedure introduced by the Companies Winding up Act, 1890—namely, how far the Court, in the exercise of its discretion, will have regard to the existence of that procedure in considering whether a supervision order or a compulsory order should be made. The petitioners were the holders for value of a bill of exchange which had been accepted by the Company, and subsequently dishonoured at maturity. Previously to the presentation of the petition an order was made in a debenture-holder's action for the appointment of a receiver and manager of the Company's undertaking and property. It was stated that the debentures comprised the whole of the assets of the Company, including the uncalled capital. After the presentation of the petition the Company passed resolutions for a voluntary winding up. Mr. Marten, Q.C., and Mr. O. L. Clare, for the petitioners, asked for a compulsory order. Mr. Swinfen Eady and Mr. Le Fanu appeared for the Company.

Mr. JUSTICE KEKEWICH said the petitioners were the holders of a bill of exchange accepted by a mercantile firm, and not only were they told that they could not now have the only remedy which the law gave them, but they were deprived of that remedy because the mercantile firm, since the proceedings were commenced, had determined to wind up their own affairs in their own way. In the case as so stated there was no doubt some little hardship and some inconsistency with what were by many regarded as common law rights. This Company, which his lordship had referred to as a mercantile firm, had managed to get, somehow or other, £50,000, or, at all events, that was the amount of their capital supposed to be represented by cash. That was apparently all gone. Certainly there was none of it left to answer the petitioners' claim, and the Company had borrowed £20,000 on debentures, and were indebted to their creditors to an amount which the petitioners said was £20,000, and which the Company stated to be £12,000. The case, therefore, appeared to be one which deserved investigation by the official receiver, who under the new legislation looked into such cases. But the Court of Appeal had held that a resolution to wind up voluntarily might be passed after the presentation of the petition, so as to put a creditor who asked for a compulsory order to the necessity of proving that he would be prejudiced by the voluntary winding up; and the Court of Appeal further held, affirming the judgment of the present Lord Justice Kay, that, under circumstances similar to those which existed in the present case—where it was not shown that there had been any misapplication of moneys between the date from which a compulsory order would take effect and that when the voluntary winding up commenced—the creditor was not prejudiced by a supervision order being made. In that case Lord Justice Kay said that he wished to prevent costs which were not positively necessary, and pointed out that if a supervision order were made any person aggrieved might apply to the Court in reference to the winding up. That view found favour with the Court of Appeal, and was applicable to the present case. No doubt a petitioner so endeavouring to interfere with the voluntary winding up was in a position of considerable difficulty, and had to act at a risk, which was a real one, as to costs; but still he had that remedy. To what extent would the petitioners be injured? An important circumstance to be regarded was this—that, as was admitted, the debentures covered everything belonging to the Company, even (according to the modern form of debenture) the uncalled capital. There must, so far as could be seen, be some uncalled capital which would go to the debenture-holders; but apparently there would be absolutely nothing coming to the petitioners. The only advantage, therefore, of a compulsory order would be that which would be gained by the public if these matters were investigated. Great as that advantage to the public might be, his lordship could not regard it as such an advantage to the petitioners that by not having it they would be prejudiced within the meaning of Section 145 of the Companies Act, 1862. On that ground a supervision order must now be made.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *April* 25, 1891.

The Electrical Production of Aluminium.—At the last meeting of the American Institute of Electrical Engineers an interesting Paper was read on "The Electrical Production of Aluminium," by A. S. Brown. There are now no less than three companies in the United States actively engaged in this work. The Cowles Company, whose process is as well known in England as here; the Pittsburgh Reduction Company, working under Hall's patents; and, finally, a company at Booneton, N.J., operating the Heroult process. Mr. Brown's Paper was largely devoted to the description of this last plant, and the results there obtained. Cheap aluminium is now an accomplished fact in this country, but the metal does not appear to have made its way into anything like extensive use, probably owing to the absence of any alloys, except that with silver, that possess at once lightness and particularly valuable mechanical properties. At the same meeting of the Institute were produced some extraordinary lucubrations by Mr. N. D. C. Hodges on the subject of protection from lightning. The author formulated the astounding proposition that the best lightning protector is one so small as to be vaporised by the discharge.

Electric Traction in Brooklyn.—A vigorous discussion is now going on with respect to the introduction of the trolley system of electric traction in the City of Brooklyn. Its advocates are very earnest in their efforts to secure permission for the erection of overhead lines, but the municipal authorities do not seem to see it in that light. It is a singular fact that in spite of every effort to put the situation in its true light, the public persistently refuse to recognise the fact that there is a distinction between an electric light circuit and an electric railway circuit as regards danger to human life. There is a deep-rooted opinion that any electrical current, except that proceeding from telegraph offices and from Edison stations, is morally certain to kill anybody who has the temerity to look hard at it, and no amount of popular education seems to produce the slightest effect in correcting this impression. Several recent accidents have created additional excitement, and, as ill-luck would have it, a couple of horses were recently killed by a telegraph wire that had fallen across an arc light circuit; consequently the daily Press can find no terms too severe for appropriate denunciation of the trolley system.

The Bell Telephone Company.—A plentiful crop of rumours are flying about as to the intentions of the Bell Telephone Company. It is stated on pretty good authority that that organisation owns an interference between Berliner and Edison, with the broad principle of the microphone as its essential feature, and proposes to settle the interference and secure a patent before its present legal rights are extinguished in 1893.

Storage Battery Traction.—The storage battery cars in New York have not yet resumed running. No one seems to be able to say definitely what is likely to become of them. Yet, in spite of repeated failures, the public sentiment in favour of storage battery traction is so strong that a successful effort would be amply rewarded. Although hope has been long deferred, there is a general feeling that the storage battery is not by any means dead.

PARIS NOTES.

(FROM OUR OWN CORRESPONDENT.)

PARIS, *May* 4, 1891.

The central station serving the Place Clichy sector was recently inaugurated in the presence of a large gathering of scientific and political notabilities, amongst whom were the Minister of Commerce and Industry, the Minister of Public Works, M. Alphand, Director of Works for Paris; M. Hult, Sub-Director; General Menabrea, M. le Royer, President of the Senate; M. Poubelle, Prefect of the Seine, and everyone of any importance in the electrical world. The honours were done by MM. Siegfried, Koechlin, Blech, Heilmann, Pirani, Soubeyran. M. Alphand started one of the 500 H.P. engines. The two following days M. Pirani gave some lectures to the engineers of the Ecoles Polytechniques et des Arts et Manufactures on the advantages of the 5-wire 440 volt system of distribution as compared with others. This 3,000 H.P. station is the first of its kind in France.

The Conseil Municipal has just authorised its officials to enter into negotiations with the Sociétés Edison, Popp, de la Transmission, and Secteur Place Clichy with respect to the renewal of the contracts for the lighting of the Grands Boulevards for 10 years at 40 centimes for 10 ampere arcs, and 57 centimes for 15 ampere arcs. The expenditure will be 348,000 francs, as against 121,000 francs for gas, but the light will be five times as great.

The result of the Municipal electric meter competition will shortly be announced. The tests of the continuous current meters are completed, and the alternate-current meters will be disposed of in a few days. In spite of the opposition of the inventors, the Committee have done well to spread the tests over a lengthy period, for long continued working has shown up many little defects not observable at the start. However, the competition will only have ascertained the condition of the electricity meter art twelve months ago, and not its present state of progress, for several meters have been much modified since the competition commenced.

The Tudor Accumulator Company has just established a factory at Lille, in order to be in a position to compete more easily with the Société Français des Accumulateurs E.P.S., which has amalgamated with the Société l'Electrique, of Brussels, which exploits the Julien accumulator. The Société pour le Travail Electrique des Métaux, owning the Laurent-Cély patent (see *The Electrician*, Vol. XXV., May 30, 1890, p. 82) has modified its style of plate so as to obtain a better hold on the active material. Its already large factory is about to be still further enlarged.

CORRESPONDENCE.

ETHER THEORY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The increased interest which certain researches and oracular utterances and writings of the past two or three years has aroused in the hypothetical philosophy of an all-pervading ether is sufficient excuse, I think, for asking a corner in your esteemed journal for some fancies of mine, which seem to have a plausible bearing upon electrical theory in those profounder depths to which the said means have largely contributed to open out the way. Starting from the postulate, which is strengthening into an axiom with every stride of research, that a surrounding medium or ether, most probably identical with that assumed in the case of radiant light and heat, is responsible for the propagation of electric energy, I wish to suggest a mode of regarding this ether and its properties which apparently has been hitherto neglected, and which seems to me to remove many difficulties from the way. What these difficulties are Sir William Thomson, Prof. Lodge, and other well-known workers in this field have of late years been showing us very clearly indeed. And that they are very real and tangible difficulties is evident from the fact that the former, even while formulating perhaps at once the completest and most elegant hypothesis of etheric structure ever advanced, acknowledged that he was still very far from satisfied; and from the candid way in which Prof. Lodge has admitted that he is yet unable to dispense with the idea of two electricities in certain sections of electrical science.

Now, the point I have to advance is that the ether being by hypothesis the disperser of energy, or, in other words, the medium upon which all potentials react in their efforts towards neutrality, the full significance of the theorem here presumed should be more thoroughly kept in view, and our further reasonings educed from it as a basis.

At present, however, the tendency of thought seems to be firmly set towards a conception of the ether as a kind of merely virgin menstruum, undisturbed and unacted upon by any impressed forces other than those immediately under consideration.

Obviously, this is too narrow and simple a view. For, by the actual nature of the fundamental hypothesis, this ether, select it from whatever region of space we will, is ever subject to a constant succession of energised impulses, so that it is illogical to conceive it as existent under any other condition. Hence, except that it can be shown that simultaneously impressed forces may not in the mean result interfere with a distinctive propagation and manifestation of each, much of our present physical theory must fall to the ground. Happily, however, the success of mathematical reasoning proves clearly enough that the presence of many impressed forces may be ignored in calculating for mean results; but the principle is not thereby established for all cases, and, in fact, the aspect of a problem may be entirely changed by ignoring these bye-influences, as I may call them.

Take, as instance, the kinetic theory of gases. The explanation of gaseous phenomena by this theory presumes the possession by the ether of a property which is otherwise not so requisite—a property which is open to the objection of being inconceivable—that of being absolutely devoid of inertia. It must offer no resistance to passage of bodies through it, else it is impossible to conceive the perpetual retention by the gaseous molecule of its primary impulse of energy. This practically inconceivable state of things is what the conception of a *still* ether leads us to in this connection. On the other hand, note how simply the less artificial conception of an *agitated* ether meets the case. By the purest natural logic it leads up to a very plausible hypothesis that the gaseous molecules *derive* and continually *renew* their kinetic energy *from* the ether agitation. A similar action is, indeed, assumed in heat theory, but it is given only a vague and partial significance. But I must not enlarge further upon this here, though it is a rich and fascinating theme.

Coming particularly and briefly to the bearing upon electrical theory, I shall, to save preliminary explanation, assume much that has lately been advanced in this direction. Granting, then, that the ether is the medium of transmission of electrical energy, we have to determine whether the consideration of an agitated, as opposed to the ordinary, acceptation of a still ether, can throw any light upon the crucial question why electrical energy is selective of a path, and a closed path? I believe it can, and rather successfully. For instance, consider a metal conductor in the agitated ether. It is continually impinged upon by the ether waves traversing the surrounding space, which, being mostly reflected, set up around the conductor a series of stationary waves or alternating succession of nodes and loops. Assume this conductor to connect a source of positive potential with a source of negative potential. The still ether particles situate in the nodes around the conductor will be in a comparatively favourable state to receive and transmit impulses of energy, for forces can act upon them without being modified by the reaction due to forces of which they may be already under the influence.

Hence we have a tendency for the energy to be transmitted along the conductor. Of course it is not asserted that there exist actually fixed nodes; the point is that there is produced a damping or reducing of the ether vibration in the vicinity of reflecting surfaces. In formulating the hypothesis we set up two postulates: first, that the most agitated ether is the best insulator of energy; second, still ether is the best disperser of energy. Also it is an obvious deduction therefrom that substances with high reflective powers should have high electrical conductivity. This is practically true in fact, for the orders of the coefficients agree fairly well, considering the difficulties attendant upon exact determinations of reflective or absorptive powers.

I place the above before your readers, hopeful of correction where I may be in error.—Yours, &c., J. WHITCHER.

TWISTED TELEPHONE LINES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Bennett's views on this question, I am afraid, differ from those of many other telephone engineers in this country. After describing the merits of the cross system he summarises the drawbacks of the twist system under five heads. I think if these drawbacks are carefully examined it will be found that they are to a large extent imaginary, or apply in a greater degree to the system he advocates.

Dealing with them in the order given, we have:—

1. *Greater first cost of the Twist System.*—To carry out the cross system it is necessary to have a number of extra insulators, special brackets to carry two insulators on one arm, extra wire for the frequent terminations and cross-connections; also, extra labour is necessary to fix all these extra fittings and cross-connections. On the other hand, with the twist method a little additional labour is required in running the wires, and with men accustomed to the work this additional amount is very slight. This, I think, rather indicates that the *crossed* method involves the *greater* first cost, and especially so when the number of metallic circuits on a line is large.

2. *Unsightliness of the Twist System.*—This, so far as the public are concerned, is unnoticeable, and, to the technical man, it is purely a question of sentiment.

3. *Greater liability to faults of the Twist Plan.*—Having in each system a similar distance between the arms, and, given the same amount of care in regulating in each case, I fail to see why two wires are more liable to get in contact when crossing each other than when they hang in the same vertical plane, as in each case there is the same vertical distance between them.

Digitized by Google

4. *Greater difficulty in finding faults in the Twist Method.*—This, I think, is entirely imaginary, as any man accustomed to the system can easily detect a fault by noticing the movement of the apparent cross in the wires as he walks along.

5. *Re-arrangement of Routes.*—This objection applies far more to the crossed method than to the twist. Suppose, that in arranging, the number of spans in any section is altered, the worst that can happen with the twist plan is that each two circuits are reversed—no very difficult matter to overcome; whereas an alteration of the number of spans in a section on the crossed system may upset the balance of the whole line, and involve an extensive redistribution of crossing points.

In conclusion, I must say that I feel very doubtful as to whether a straight ten mile loop will kill *all* overhearing and telegraphic induction; also that I did *not* know that two single lines could be run on the same arm for a mile without experiencing any cross-talk; in fact, if these lines are pretty free from other noise, the cross-talk will be quite appreciable.—Yours, &c.,

J. W. ULLETT.

May 5, 1891.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: My attention having been directed to the article on Twisted Telephone Lines in your issue of the 17th ult., and to Mr. A. R. Bennett's remarks thereon in your issue of the 1st inst., I should feel obliged if you will allow me to correct the impression conveyed with respect to the points at which the wires on the Midland used for telephone purposes are crossed. Such wires as have been erected in this manner have been usually crossed at every fourth pole, but it will be evident that the crossing need not, as pointed out by Mr. Bennett, be at every fourth, much less at *every* pole.

The position of the crossings should, in point of fact, be governed, as it appears to me, by the neighbouring wires. If we take the case of two telephone wires erected on poles carrying one other wire, this other wire being used, say, for a Wheatstone, it would only be necessary to cut and cross the telephone wires, say, midway of their entire length, in order to counteract the influence upon them by the Wheatstone wire.

Again, suppose a similar wire passing along the poles carrying telephone wires for a short distance only, it would then be necessary to cut and cross the telephone wires at the point where the interrupting wire parted from the telephone wires, and at a point midway in the section traversed by the telephone wires as well as by the Wheatstone wire.

Of course, where you have many wires from which induction may arise, it is desirable to lay down a general governing principle such as shall meet the general conditions to be met with, and crossing the wires at every fourth pole certainly ought to meet this condition.

Some reference is made to "interruptions" where wires are crossed in this manner. Although we have had experience of such crossed wires for many years, I cannot call to mind any interruptions which have occurred; nor do I think the system likely to give rise to interruptions. The cross connections are made by open wires from one wire to the other, an insulator being employed between the two connections in order to keep them from contact with the pole where such is found necessary.—Yours, &c.,

W. LANGDON.

WIRING SYSTEMS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: To many of us students who sat for the City Guilds' Exam., on Wednesday, the 29th ult., the question as to what were series-multiple and multiple-series, and also series-parallel and parallel-series, much perplexed us.

Again, the term multiple-arc is to me intensely vague. Could not the word arc be entirely abolished, and for multiple substitute parallel? Why do not electricians confine themselves to simply the terms series and parallel, as I think every ordinary process of wiring, &c., can be explained by their use alone.

On page 31 of the current edition of "Electric Light Fitting," by Urquhart, the following diagram occurs:—

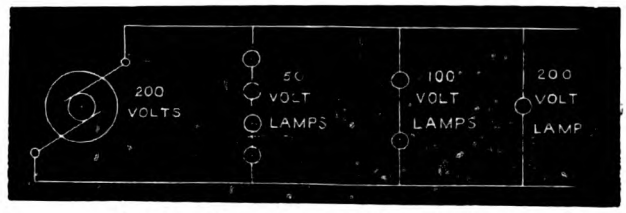

FIG. 44.—Diagram of Series-Multiple Circuit

And on page 134 (*i.b.*):—

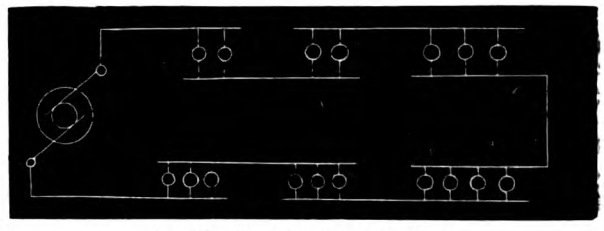

FIG. 47.—Multiple-Series Method.

Are these correct? I am of opinion that Fig. 44 should have been termed the parallel-series method, and Fig. 47 series-parallel.

Mr. Urquhart, in his preface, addresses himself to "intelligent men already engaged in the work of electric lighting, or training for it," and goes on to say, "he does not attempt to teach trained electrical engineers any part of their business, as these gentlemen need no instruction from books."—Yours, &c.,

A. FREYER EVANS.

Newport, Mon.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

"THE ELECTRICIAN"

ELECTRICAL TRADES' DIRECTORY & HANDBOOK for 1891.

The 1891 edition of our well-known Directory and Handbook is ready, price 5s., postage extra. The book consists of over 900 pages, and has entailed this year a heavy amount of work. The HANDBOOK DIVISION contains a mass of most useful information. The DIRECTORY DIVISION consists of 430 pages, and contains a very carefully compiled Alphabetical and Classified List of Firms and Persons engaged in the Electrical and Allied Trades in all parts of the world. This Division has been corrected up to date, and the book is thoroughly reliable, the very numerous changes which take place at the beginning of the year being incorporated. By the aid of this Directory, makers of Electrical Machinery, Apparatus, Instruments, Fittings, Sundries, Novelties, and other goods, may safely communicate direct with probable customers without the annoyance and great expense consequent upon using books which are mere lists of Members of Scientific Societies repeated again and again. The Colonial and Foreign Division of this Directory will be found extensive and reliable. *Orders should be forwarded at once.*

In the course of a few weeks "The Electrician" Company will publish "THE ELECTRICIAN" PRIMERS in two volumes, price per volume 2s. paper covers, 2s. 6d. cloth.

THE FRANKFORT EXHIBITION.—As announced in our advertisement pages, the Frankfort Electrical Exhibition will open on May 16th, and it will interest many of our readers to know that the Great Eastern Railway Company are making arrangements for the comfort of intending visitors to Frankfort. The Continental booking-office at Liverpool-street station will be open daily from 9:30 a.m. till 8 p.m., and an attendant accompanies the train as far as Harwich, who will give passengers any information and assistance they may require. The Company's passenger steamers (11 in number) are all lighted by electricity. Applications for deck cabins and saloon berths on the Company's steamers should be addressed to Captain Howard, of Parkestone-quay, Harwich.

Digitized by Google

Special facilities are offered to passengers from the North, the Midland counties, and the North-West of England over the Great Eastern Company's joint lines. The Company issue an exhaustive time-table giving a map showing the route and full detailed particulars. Negotiations are in progress for the running of excursion trains to Frankfort from all parts of Germany at cheap fares while the exhibition is open.

MESSRS. CHRISTY BROTHERS.—The firm of Christy, Son, and Norris, electrical engineers, of Chelmsford, has dissolved partnership, and the business will be carried on in future under the style of Christy Brothers.

PARTNERSHIP NOTICE.—We are informed that Mr. Gastrill Wilkins, of the Wire Rope Works, High-street, Wapping, has taken into partnership Mr. S. H. Hudston, for many years with Messrs. Richard Johnson and Nephew; and that the wire-rope manufacturing business will be continued under the style of Messrs. Wilkins and Company.

MESSRS. E. L. BERRY, HARRISON, AND COMPANY.—Mr. E. L. Berry informs us that he has entered into partnership with Mr. F. Harrison, of Liverpool, and that they will carry on business under the above style at Lyric-chambers, Whitcomb-street, W.

THE CAMBRIDGE SCIENTIFIC INSTRUMENT COMPANY.—We have received the illustrated catalogue of the manufactures of this firm. The excellence of the workmanship, and the careful scientific supervision of the design, of their instruments is well known. Their speciality is in apparatus for physiological research, but their list contains a considerable number of electrical instruments and includes "quartz fibres." We understand that this Company are engaged in designing some apparatus for the Electrical Standards Committee of the Board of Trade.

THE LIGHTING OF LAMBTON CASTLE.—The Earl of Durham has decided to thoroughly reorganise the electric-lighting arrangements at Lambton Castle. The existing machinery has been found to be of insufficient power to light the Castle satisfactorily, and an entirely new electric generating plant—comprising two "Cornish" boilers, each of 25 nominal H.P., and two "Parsons" steam turbines and dynamos of the new improved type, with automatic expansion, each capable of supplying 32 kilo-watts, is to be erected by Mr. A. A. Campbell Swinton.

SHIP LIGHTING.—Messrs. J. D. F. Andrews & Co. have installed the electric light on the new Japanese Royal Mail steamer "Jenkia Maru," built by Messrs. Napier, Shanks, and Bell. Messrs. Andrews' concentric wiring system has been adopted. The installation is for 150 16 c.p. lamps. The dynamo is driven direct by an open vertical engine with Pickering governor.

WIRE TABLES.—Messrs. W. F. Dennis and Company are issuing a new edition of their tables relating to the various gauges employed in this country and on the Continent. A useful feature is a table showing the breaking strain for iron and steel wire of various brands and of the Standard Wire Gauge.

MR. WILSON HARTNELL.—We learn that this gentleman, who has recently opened at 11, Queen Victoria-street, E.C., has been appointed by Messrs. Cole, Marchent, and Morley, engineers, of Bradford, their agent for all classes of general engineering, oil mill machinery, &c. Mr. Hartnell has also been appointed agent to Messrs. James Lee and Sons, leather belting manufacturers, of Hipperholme, near Halifax.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

April 20, 1891.

6,767. W. LUCAS and T. A. GARRETT. London. Improved means for the production of ozone electrically.

6,773. L. von ORTH. London. Improvements in apparatus for signalling time, and for regulating clocks by electricity.

6,774. H. de REUTER and E. E. H. GOWER. London. Improvements relating to electric conductors.

6,782. H. L. CALLENDER. London. Improvements in dynamo electric machines and electric motors.

6,793. P. C. E. CHAMPION. London. The application of electricity for the production of pyrotechnic and other similar effects and apparatus therefor.

April 21, 1891.

6,831. A. L. PARCELLE. London. Improvements in dynamo electric machines.

6,846. S. R. LINVILLE. London. Improvements in printing telegraphs.

6,847. S. R. LINVILLE and L. F. HETHNANSPERGER. London. Improvements in printing telegraphs.

6,870. J. W. T. CADETT. London. Improvements in electric motors.

6,881. J. E. WALCOTT. London. An improved method of and apparatus for covering electric wires.

6,890. F. B. ASPINALL. London. Improvements in and connected with electric locks.

SPECIFICATIONS PUBLISHED.

1890.

8,474. MCEVOY. Electrical switches. (Price 8d.)

8,534. DE BENARDOS and Others. Secondary batteries. (Price 4d.)

8,720. WALTER. Electro-magnetic railway brake.

9,602. SIEMENS BROTHERS & Co., LIMITED (Siemens and Halske). Distributing electrical energy. (Price 8d.)

12,169. DESRUELLES and CHAUVIN. Measuring electrical energy. (Price 8d.)

20,115. BARRETT, C. A. & A. Coin freed dynamo-meters. (Price 8d.)

1891.

3,191. DOLIVO-DOBROWOLSKY and Others. Distributing electricity. (Price 11d.)

WEST COAST OF AMERICA TELEGRAPH COMPANY (LIMITED.)

The following report of the Directors of this Company arrived too late for classification:—

The balance sheet and revenue account for the year ending December 31, 1890, show a gross income of this Company of £65,323 15s. 4d., against £84,457. 13s. 1d. for the year ending December 31, 1889. The addition of £517. 10s. 3d. brought forward from the previous year makes a total of £65,841. 5s. 7d., and, deducting from this the debenture interest and all other charges, as well as the interim dividend of 3s. per share paid in July last, there remains the sum of £22,195. 12s. 11d. Out of this amount the Directors have transferred £16,000 to the reserve fund, bringing it up to £80,000, written off £1,000 from the value of the repairing steamer "Retriever," and now recommend the distribution to the shareholders of a final dividend for the year 1890 of 2s. per share, payable on the 20th inst., leaving £2,195. 12s. 11d. to be carried forward.

The cable with which the Central and South American Telegraph Company intends to compete with your line has been laid, but is not yet working in its entire length, owing to the revolution which has broken out in Chili.

In accordance with what was suggested at the extraordinary general meeting of shareholders, held on September 1st last, negotiations have been commenced with the object of strengthening the position of the Company, and opening for it a source of revenue not otherwise obtainable.

The Directors look upon the present as a period of transition, but expect that these negotiations will lead to a satisfactory result; meanwhile they do not consider it prudent to make a larger division of profits than that recommended in this report.

During the Chilian Revolution, which broke out in January last, and unfortunately, still continues, the cables of the Company have been cut by both Government and Opposition forces; the Company has, however, received partial compensation for the interference with traffic. The repairing steamer is in readiness to connect the sections cut as soon as hostilities come to an end.

Mr. Henry Roberts and Mr. Alfred Marshall are the Directors retiring in rotation; both are eligible and offer themselves for re-election. The auditor, Mr. J. Weise, of Messrs. Turquand, Youngs, Weise, Bishop and Clarke, retires, and is eligible for re-election.

COMPANIES' MEETINGS & REPORTS.

Brazilian Submarine Telegraph Company (Limited).

The thirty-fifth ordinary general meeting of the shareholders of the Brazilian Submarine Telegraph Company (Limited) was held at Winchester House, Old Broad-street, on Wednesday, under the presidency of Sir James Anderson.

The SECRETARY (Mr. Richard Collett) having read the notice calling the meeting and the minutes of the last meeting (which were signed by the Chairman as correct), the report of the Directors was taken as read.

The CHAIRMAN then said: I will ask your leave, before proceeding to the financial part of the report, to refer to paragraphs 4 and 6, in which you will find that we have lost from among us our noble Chairman, Lord Monck, and Sir Thomas Fairbairn. Their City engagements became too onerous for them, mainly, I am sorry to say, on account of prolonged ill-health, and they desire to be relieved of these obligations as much as possible. I am sure you will join with me in expressing your wishes to these gentlemen that the repose they are now seeking will restore their health, and that they will have that calm and comfort which they desire, and which, I am sure, they thoroughly deserve. You see also, in paragraph 6, that we have filled these vacancies by the election of two perfectly unexceptionable gentlemen, namely, Lord Sackville Cecil and Mr. J. Denison Pender, who have for some years been among us, acquiring that knowledge of our ramifications and negotiations which, I am sure, are far more numerous than the shareholders are aware of. I am glad to find that we can meet with young gentlemen of experience to take the places of those of us who are going very fast behind the scenes. Those of you who are watching the passing away of the senior members of these Boards must be struck with the great number who are leaving us from one cause and another—mostly bad health and death—and how necessary

Digitized by Google

it is that we should fill up their places by young men with heads on their shoulders, and with some "go" in them to meet the contingencies that are fast arising. I propose, in the observations which I am about to address to you now, to make some remarks indicating the necessity for a strong Board. I am not going to alarm you, for I am not alarmed myself; nor do I take a despairing view of what is going on. It would, however, I think, be wrong if I were not to say that we have arrived at a period in our history which may be termed a turning-point, and, perhaps a crisis. For all that, I am not anxious. I believe that we can give as good as we get, and those who are making opposition lines will find that they are opposing two companies who are well up in their work. If you look at that map you will see what I mean. A line has been made from Charillos, on the west coast of America, to Valparaiso, which is meant to oppose the West Coast of America line, and, if those connected with it could get all they desire, they will come across the Andes to Buenos Ayres, and get into our region. The Brazilian Government have granted a concession for a cable from Pernambuco to Senegal. That is a project which has been talked of for 16 years, and we are not alarmed about it. There is, however, a line that is being made which has some significance. It is laid between Cuba and Dutch Guiana at present, and they mean to connect Brazil and North America. We do not, however, stand afraid of that either. Our Company has duplicated lines, and our partners, the Western and Brazilian, are duplicating their cables also. We are duplicated all the way from England to Pernambuco, and the Western and Brazilian are now duplicating their line from Pernambuco to Santos. If we duplicate as we are doing, and have the duplex applied to our cables, we are very strong. It has been the policy of this Board since the inception of the Company some 18 years ago to lay by a large reserve. Fortunately for us, our reserve has reached a point at which we have duplicated the whole system without adding to our capital, excepting in a small way, by Debentures which are fast being paid off. Besides that, we have in our bank in securities upwards of £400,000 as a substantial addition to a growing reserve. Now, you would naturally expect when we are having such fine traffics—largely owing, I daresay, to the late crisis in Argentina and the war in Chili—that we should give you a larger bonus, and we shall have to consider the question of bonus prior to our next meeting; but I will urge you to be satisfied with what I call a good dividend, and to encourage your Directors to amass as much reserve as possible while times are good, because, inevitably, when these lines are laid, they can have no other policy but to reduce the tariff, and that, of course, will reduce our dividend—at all events, will reduce our power of laying by a good reserve if we keep up a good dividend. We must, therefore, make hay while the sun shines; and such is the policy of your Directors, which you will, no doubt, support. Having, as I said, duplicated our lines and when we have duplexed them, we shall be quite in a position to meet all comers whenever they try to make any experiments with reduced tariffs. We can come down as soon as they can. Possibly we might have come down sooner but for these lines threatening us. We must lay by what money we can, and pay you as good a dividend as possible while we have the chance. So far as our calculations go, taking the worst view of it, even with these competing lines made and the tariff reduced, I do not despair of our paying a good dividend and making a fair addition to the reserve. That is a good position to be in. With a large reserve of carrying force, a large reserve of sovereigns at your bank, and with the power of extending your system more, perhaps, than our opponents are aware of, into some chinks of their own armour, which they are not thinking of now, you must, I think, see that this is a position which makes our Company somewhat invulnerable. At all events, we have no necessity to be afraid of our opponents. Naturally, we cannot hope to keep a monopoly for ever; but we possess all the elements which make telegraphy a success, in my opinion—that is, having duplicate cables, a large reserve of carrying force, and a reserve at our bankers'; and with a trained staff of telegraphists, ensuring accuracy and speed, I think we have as good a chance of continuing our existence profitably as any Company that can be imagined. I do not propose to describe what we think we can do by-and-by by way of extensions, but we are not going to be idle. I shall now refer to some points in the financial part of the report. Abstract A, dealing with the general expenses in London, is practically without any feature calling for remark. Abstract B shows an increase of expenses of £1,092, mainly due to the following items:—A new sanatorium at St. Vincent, costing £600. We are suffering a great deal at our different stations from the want of good sanatoriums and the want of sanitary arrangements, and we think it is our duty as Directors to keep our young men alive and give them what accommodation we can to compensate them for spending their lives at these stations. We have spent £276 at Madeira, on improving the sanitary arrangements. Mr. Fuller told me this morning that Madeira is the most unhealthy station we have, though people go there to recover their health. We have spent £100 at Pernambuco, mostly on replacing timber beams in the staff quarters. On new and spare instruments, on account of the increase of traffic, we have expended £336, and we have made some increase to our staff to deal with the traffic, which increased by 16,000 messages last year. In the revenue account there is an item of £907 for legal expenses. This has arisen from a question of Brazilian law differing from English law, and the outcome of a transfer of shares under a power of attorney given by a shareholder in Brazil. We were advised to contest the action brought against us, and we have been contesting it since 1885. Subsequently the plaintiff sought a compromise, and, having regard to the uncertainty of the law and the greatly increased cost of continuing the action, our solicitor urged us to agree to a compromise. That item has, therefore, been met, and it is better to have done so than to have gone on building up legal expenses. In substance, then, gentlemen, our revenue has increased by £22,244; our messages from all sources by 16,000, and our expenses by £1,093. Mr. Dawes (our solicitor) reminds me that this item of legal expenses, amounting to £907, includes compromise, and was not all legal expenses. In paragraph 7 of the report we refer to the picking up of our cable off Madeira, and I think it only right to tell you—and I give credit for the fact to our men at Madeira—that the cable was repaired by the staff with local resources. The cable that was picked up by the Telegraph Construction and Maintenance Company's ss. "Scotia," was 18 years old, but after they got on to smooth bottom it was found to be as good as when it was laid. I think I have now referred to all the main points in the report, and I have held out some warning—not as a threat, but only as showing you the necessity of husbanding our resources, and not paying away too much until we see what we can do. I think I have also shown you that our rivals have their work before them. With these observations I now move:—

"*That the report of the Directors and the accounts to December 31st, 1890, now submitted, be approved and adopted.*"

The Hon. W. ST. JOHN F. BRODRICK, M.P.: I have much pleasure in seconding the resolution.

The CHAIRMAN expressed his readiness to answer any question; and, in replying to Mr. Newman (who referred to the item of £1,835 for depreciation in the value of the stock of spare cable), stated that after a cable had been in tanks and been turned over two or three times it depreciated. It, however, came in afterwards for repairs, and would be put in at the reduced cost. He then put the resolution, which was unanimously agreed to.

On the motion of Mr. W. T. ROUGHTON, seconded by Mr. T. M. NEWMAN, a cordial vote of thanks was passed to the Chairman and Directors.

The CHAIRMAN briefly acknowledged the vote, and the proceedings then terminated.

Great Northern Telegraph Company of Copenhagen.

The following shows the working account of this Company for the year 1890:—

	£	s.	d.	£	s.	d.
RECEIPTS.						
Balance on the 31st December, 1889				46,722	5	10
Traffic receipts	291,517	0	10			
Less loss on exchange	10,605	7	10			
				280,911	13	0
Interest				21,327	0	9
Sundries				6,422	3	6
				£355,383	3	1
EXPENSES.						
Salaries and wages				39,686	19	1
Expenses of Stations, Offices and Agencies				8,721	18	9
Ordinary supervision and maintenance of the sea and land lines, and repairing steamers "H. C. Oersted" and "Store Nordiske"				13,375	19	9
Instruments and cells				2,860	13	3
Maintenance of Company's buildings				454	9	9
Travelling expenses				585	17	5
Bank Commission, &c.				3,564	7	10
Sundries				305	10	2
Total Expenses				69,555	16	0
Five per cent. interest on debentures	12,500	0	0			
Amortization of 250 debentures	25,000	0	0			
				37,500	0	0
				107,055	16	0
The Board propose to distribute the balance as follows:—						
Reserve and renewal fund				66,666	13	4
Pension Fund of the staff				2,777	15	7
Remuneration to the board of directors				1,500	0	0
Interim dividends already paid				75,000	0	0
Proposed final dividend				54,166	13	4
Balance carried forward				48,216	4	10
				£355,383	3	1

The following is an abridged report of the proceedings at the general meeting held at Copenhagen on the 25th of April, 1891; F. Zahle, Esq., presiding.

The CHAIRMAN of the Company, C. F. Tietgen, Esq., in rendering an account of the working during the year 1890, referred to

The Company's Cables, which, he said, had been subject to about the same number of interruptions as during the previous year, viz., 27 in all; 14 on the European and 13 on the Far East Cables. The Company's cable steamers had, in consequence, been fully employed; in fact, the "H. C. Oersted" had been on active service for 166 days, and the "Store Nordiske" for 163 days, of which latter, however, 27 days had been for account of others. The cables which had suffered most from these interruptions were the North Sea cables, connecting Great Britain and France with Scandinavia.

New Cables.—Having regard to the numerous interruptions, the Company had every reason to congratulate itself upon the decision arrived at in 1890, to lay a new direct cable between England and Sweden, and also a second cable between France and Denmark. Although there were other business matters which had required urgent attention, nothing had been left undone to accelerate the realisation of these projects. As under the existing agreements with the British and Swedish Governments only a few minor points had to be settled, the laying of the new English-Swedish cable had already been accomplished in November last. The cable, which was 509 nautical miles long, and connected Newbiggin-on-the-Sea with

Digitized by Google

Gothenburg in Sweden, had been manufactured and laid by the Telegraph Construction and Maintenance Company, Limited, of London, who had carried out the work very successfully and to the entire satisfaction of the Company. The new line was opened for traffic on the 23rd November last, and had been working very satisfactorily up to the present. The negotiations with the Danish, and especially with the French Governments, relating to the laying of the new cable between Calais and Fanoe in Denmark, had been of a somewhat more protracted nature, owing to the necessity of applying for a prolongation, and to some extent modification, of the existing Conventions. The new Convention granted by France, by which the privileges accorded to the Company had been prolonged until the 1st January, 1916, had actually been signed on the 1st October last. As, however, the sanction of the French Chambers had not been obtained till very recently, the Company had reluctantly been obliged to postpone this important undertaking until the current year. Although the delay was to be regretted, still it had this advantage, that the cost of the new cables could be spread over two financial years, and the investments already made on account of the reserve fund left intact.

Sale of portion of the Korea Cable.—Some time ago an agreement had been concluded with the Japanese Government, by which the length of the Company's cables in the Far East would be slightly reduced. By this agreement, two short lengths of cable (57 nautical miles in all), laid by the Company in 1884 between the Japanese Islands of Kiusiu, Iki, and Tsushima, had been transferred to the Japanese Government, who were anxious to add them to their internal telegraph system. Although the Company would have preferred to retain the ownership of these cables, which formed an integrant portion of the line between Japan and Korea, they had ultimately yielded to the wishes of the Japanese Government, who had always given the Company very marked proofs of sympathy and goodwill.

New Premises in Copenhagen.—The building of the Company's new offices in Copenhagen had made so much progress that they were expected to be ready for occupation before the end of the year.

The Traffic Receipts had amounted to about £280,000. which was a higher figure than had been reached in any previous year. This was principally due to the temporary rise in the value of silver, which had enabled the Company to effect their remittances from the Far East at exceptional rates of exchange. But even apart from this the net profits had exceeded those of any previous year.

International Telegraph Conference at Paris.—The great event of the year had been the International Telegraph Conference, which was held at Paris from the 15th May to the 21st June last year, when the European tariffs had been revised, and fixed for a period of five years from the 1st July, 1891. The Company, which had, as usual, been represented by the Managing Director, Captain E. Suenson, had agreed to participate in some very considerable tariff reductions. Thus, the rates between Great Britain on the one side and Denmark and Norway on the other, would be reduced from 4d. to 3½d. a word, between Great Britain and Sweden from 5d. to 4d., and between Great Britain and Russia from 6½d. to 5½d., &c. That the Company could meet these and similar tariff reductions with comparative equanimity, was principally due to the prudent financial policy which they had pursued for years, in applying a considerable portion of the receipts to an extraordinary amortization of the debenture loan of 1881. This had been entirely paid off on the 1st January last, and the expenses towards the amortization of, and interest on, debentures had been reduced from £49,250 in 1889 to £37,500 in 1890, and would henceforth only amount to about £20,000. It was to be hoped that the saving thus effected in the yearly expenses of the Company would amply counterbalance the before-mentioned tariff reductions during the period which would elapse before the natural development of the traffic could gradually effect the same object. It might also be considered an advantage that the new tariffs would not come into force until the 1st July next, the loss incurred during the first twelve months being thus spread over two financial years.

Distribution of Profits.—Owing to this favorable position, the Board of Directors had been enabled to recommend that the extra dividend, which, after the Berlin Conference had been reduced to 5s., be increased by 2s. 2d., making the total dividend for the year 17s. 2d. per £10 shares, or about 8·60 per cent. They also recommended to add a somewhat larger amount than usual to the reserve fund, in order to meet the heavy expenses in connection with the laying of the new cables.

Obituary.—From the foregoing remarks it would appear that the year 1890 had been a very active one, and it might at the same time have been called a very fortunate one in every respect had the Board of Directors not sustained a sad and irreparable loss through the demise of two of their collaborators. Mr. L. P. Holmblad, who had been on the Board ever since the formation of the Company, died at Copenhagen on the 16th November last, deeply lamented by his fellow-directors and by all who knew him. Mr. H. G. Erichsen, who had taken a most active part in the promotion of the Company, and whose enlightened mind and great business capacity had been of invaluable service to the Company, died on the 6th December last, in London, where he had acted as the Company's representative for a great number of years. He had been succeeded by Mr. F. C. C. Nielsen, the Company's manager in London.

The report and balance-sheet, together with the propositions as to the distribution of the balance, were unanimously adopted.

The retiring Director, A. Garde, Esq., was re-elected Director; and A. Berner, Esq., and S. Bille, Esq., were re-elected as Auditors.

Seven shillings and twopence per £10 share, representing the final dividend for 1890 upon the Great Northern Company's Stock, are now payable at the Company's bankers, Messrs. C. I. Hambro & Son, No. 70, Old Broad-street, London, E.C., against Coupon No. 21.

Oriental Telephone Company (Limited).

An extraordinary general meeting of this Company was held at the offices of the Company, 14, Austin Friars, E.C., on Wednesday, the 6th inst., Mr. Wm. Addison in the chair, when the following resolution, which was passed at the meeting held on April 15th, was confirmed as a special resolution, viz.:—

"*That the following resolution passed at the ordinary general meeting of the Company held on April 15th*, 1891, *be confirmed as a special resolution*":—

"*That the Company's Memorandum of Association be altered as follows*:—

"*By adding at the end of paragraph (b) of Clause 3 the words 'or generation, employment, or utilisation of electricity or magnetism.'*

"*By inserting after the said paragraph (b) the following additional paragraph*:—*(bl), 'To carry on any business or manufacture relating to the generation, employment, or utilisation of electricity or magnetism, or the apparatus connected therewith.'*"

This was moved by the CHAIRMAN, and seconded by Mr. HENRY GRÈWING, and carried.

Kensington and Knightsbridge Electric Lighting Company (Limited).

The annual general meeting of this Company was held on Monday, the 4th inst., at 1, Great George-street; Mr. Granville R. Ryder in the chair.

The SECRETARY (Mr. R. S. Erskine) having read the notice convening the meeting, and the minutes of the last meeting,

The CHAIRMAN, in moving the adoption of the report and accounts, said that during the year ending 31st December last about four miles of mains had been laid, leaving only about three-quarters of a mile to be laid to complete the whole of the Company's compulsory area. During the year the number of houses and shops connected with the Company's system had increased from 147 at the end of 1889 to 291 on December 31st, 1890; while the number of lamps calculated on the usual basis of 8 c.p. had increased during the same period from 11,794 to 25,535. The shareholders would probably like to know that at the end of April the number of customers had increased still further to 342, and the number of lamps to 30,455, which was very satisfactory. With regard to the accounts, which, on the suggestion of the auditors, had been prepared in a more simplified manner, he did not know that there was any special item requiring explanation. What would perhaps most interest the shareholders was, what were the prospects of the Company It was true that customers had not come forward to the extent they would have liked, but he was hopeful of the future, and thought it was only a question of time when the business of the Company would largely be increased. The secretary had been for some time making careful calculations as to the average gross income from each lamp per annum, and he found it worked out at 10s., which, if they had 40,000 lamps, would produce £20,000. This they reckoned would give a net profit of from 35 to 40 per cent., which, after paying the Preference shareholders, would leave sufficient to pay a good dividend on the ordinary shares. With reference to the powers the Directors proposed to take for raising additional capital, they had carefully gone into the question before deciding to ask for these further powers, and the shareholders might be perfectly certain that the money would not be spent unless the Directors could see their way to doing so in a satisfactory manner. The secretary had calculated that an expenditure of £10,000 on plant, mains, &c., would add 10,000 lamps, which meant a net profit of £2,000. The Directors asked for a free hand in the matter of the new issue. Under the Articles of Association they had powers to issue debentures or debenture stock without the sanction of the shareholders, but they proposed to do the same thing in another way. They only proposed to issue £10,000 of new shares at first. It was satisfactory for the shareholders to know that the profits of the Company for the first three months of the year were sufficient to pay 6 per cent. to the Preference shareholders for the half-year, and to carry forward a small balance.

The motion for the adoption of the report and accounts was seconded by Mr. G. H. HOPKINSON, and, after some remarks by Mr. KILLINGWORTH HEDGES and Mr. PARKER YOUNG, it was carried.

The CHAIRMAN then proposed:—

"1. *That the capital of the Company be increased by the creation of* 10,000 *new shares of* £5 *each, to be called Second Preference Shares.*"

"2. *That the Second Preference Shares shall be issued at such times, for such amounts, under such conditions, and at such rate of interest, as shall be determined by the Directors.*"

"3. *That the holders of the Second Preference Shares shall have no right of voting at any general meeting in respect of such shares.*"

Mr. HOPKINSON seconded.

Mr. R. E. CROMPTON, in the course of a few remarks, spoke hopefully of the prospects of the Company. There had been a hanging back on the part of consumers at the beginning of the year, but they were now going on at a better rate. If the ordinary shareholders had patience, they would yet see their investment paying a good interest, and he was sure they would ultimately find their shares a valuable property.

After a few remarks from a SHAREHOLDER, who complained that the estimated expenditure had been much exceeded, which, however, was explained by the CHAIRMAN, the motion was carried.

On the proposition of Mr. HOPKINSON, seconded by Mr. PARKER YOUNG, Mr. Granville R. Ryder was re-elected a Director, a like compliment being paid to Mr. R. W. Wallace, on the motion of Mr. Granville R. Ryder, seconded by Mr. Killingworth Hedges; and the auditors, Messrs. Lovelock, H. W. Whiffen, and Dickenson, having been re-appointed, the meeting terminated with the usual vote of thanks to the chair.

Submarine Cables Trust.

The twentieth ordinary annual meeting of the certificate holders in the Submarine Cables Trust was held at the offices, Winchester House, Old Broad-street, on Tuesday, under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY (Mr. Lewis Wells) read the notice convening the meeting, and the minutes of the last general meeting; and the report of the Directors was taken as read.

The CHAIRMAN then said: Our revenue for the past year amounted to £23,666, as against £23,094 in 1890, showing an increase of £572 Of this increase £264 arises from a small profit made by the trustees on a temporary investment of their funds, and the remainder from an improvement in the dividend received on their investment in Anglo-American Stock. Our expenses for the year amounted to £1,175, as compared with £1,274 in 1890, showing a saving of £99. Our expenses for the years 1888 and 1889 were over £1,380. We are, therefore, working at the rate of £205 per annum less than formerly, the economy shown being mainly due to our not having filled up the vacancy on the Board caused by the death of Sir Daniel Gooch. The small increase in revenue, coupled with a decrease in expenses, may be regarded as satisfactory. The accounts before you show that we are now earning 6¾ per cent. on the amount of our outstanding certificates. Our coupons, as you all know, are six months in arrear. While we are in this position the certificate holders will receive, in addition to the usual 6 per cent., as much as possible in reduction of the overdue coupon. We propose paying £1 on the 15th inst., and the balance of £2 as soon as we have sufficient money in hand for the purpose. As you are aware, this Trust is dependent for its success on the dividends it receives from the Submarine Telegraph Companies whose stocks it holds. During the time when we fell behind with our coupons there was great competition in connection with the Atlantic cables, and this very much reduced the dividend we received from the Anglo-American Company. Submarine cables are now doing better, and as they improve, and their revenues and dividends increase, so this Trust will benefit to a corresponding extent. We do nothing of ourselves. We have simply to watch carefully the proceedings of other companies, and I think I may say that at the present moment the companies in which we hold a large interest are, all round, in a very satisfactory position. With these remarks I beg to propose:—

"That the report and accounts of the trustees, now submitted to the meeting, be approved and adopted."

The Most Hon. the Marquis of TWEEDDALE: I beg to second the motion.

The CHAIRMAN: If any gentleman desires to put any question to me I shall be glad to answer it.

No one rising to address the meeting, he put the resolution in the usual way, and declared it carried unanimously.

On the motion of Mr. BLACKLEY, seconded by Mr. K. Anderson, the retiring auditors, Mr. John G. Griffiths and Mr. John Gane, were re-elected for the current year.

The CHAIRMAN: That is all the business. I might add just a word in regard to this Trust. You are aware that it is very much on the principle of a tontine. I do not see how I can hope that many of those who are now before me can come in at the winding up. When we can pay our coupons up to date our surplus revenue will be employed as formerly, in buying up certificates, and eventually this affair must fall into the hands of a very few persons.

A cordial vote of thanks was then passed to the Chairman and Directors.

The CHAIRMAN: I am very much obliged to you for the compliment. As you know, we happen to be very much interested in all the other companies. We know, therefore, how they are going on; and, indirectly, we are able to watch after the interest of this Trust from day to day. I think I may venture to assure you that we are now in an improving position, and I look upon this concern as a very good investment indeed.

Western and Brazilian Telegraph Company (Limited).

The following is the report of the Directors to be presented at the twenty-first ordinary general meeting of the Company, to be held at Winchester House, Old Broad-street, London, E.C., to-day (Friday), May 8th, at 12 noon:—

The total earnings amount to £108,817. 10s. 5d., as against £86,403. 0s. 7d., showing an increase of £22,414, 9s. 10d., compared with the half-year to December 31, 1889. The working expenses amount to £37,200. 2s. 4d., as against £40,391. 11s. 9d., a decrease of £3,191. 9s. 5d. Including the amount brought forward from June 30, 1890 (£5,751. 7s.), and the dividend received upon the shares held in the "Platino" Company, the balance to the credit of the revenue account is £86,602. 5s. 1d., from which has been deducted £13,164 for debenture interest, and £5,936 for the debenture redemption fund, leaving £67,502. 5s. 1d., of which £20,000 has been placed in the reserve fund. The Directors now recommend the payment of a dividend of 9s. per share, free of income tax, on the ordinary shares for the half-year, making with the dividend paid in November last, £5 per cent. for the year, leaving a balance of £6,070. 6s. 1d. to be carried forward. In the case of shares which have been divided into "preferred" and "deferred," 1s. 6d. per share of the dividend now recommended will be payable to the "preferred" shareholders, and 7s. 6d. per share to the "deferred" shareholders.

The second annual drawing of the A and B debentures took place at the Company's offices on January 16th last, in the presence of Mr. W. W. Venn, jun., Notary, when debentures amounting to £11,900 were drawn, and have since been paid off at par.

A contract for the duplication of the Company's lines between Pernambuco and Santos has been entered into with the India Rubber, Gutta Percha and Telegraph Works Company (Limited). The ship carrying this cable will leave in a few days.

Since the last report ten "Platino" shares have been exchanged for six shares of this Company.

The dividend warrants will be posted on May 15, 1891.

The retiring Directors are Mr. W. S. Andrews and Lord Richard H. Browne, who offer themselves for re-election. The Auditors, Mr. John Weise and Mr. John G. Griffiths, retire, and are eligible for re-election.

West India and Panama Telegraph Company (Limited).

The following is the report of the Directors for the half-year ended 31st December, 1890, to be submitted to the twenty-eighth ordinary general meeting, to be held at Winchester House, Old Broad-street, E.C., on Wednesday, the 13th inst., at 12 o'clock:—

1. The amount to credit of revenue is £43,978. 19s. 8d. (against £42,768. 0s. 1d. for the corresponding half-year of 1889), and the expenses have been £21,898. 3s. 11d. (against £27,071. 7s. 0d. for the same period in 1889), leaving a balance of £22,080. 15s. 9d., which, with £322. 6s. 8d. brought from last account, make a total of £22,403. 2s. 5d., with which it is proposed to deal as follows:—

	£	s.	d.
First Preference Shares—			
Dividend, 6 months to 31st Dec., 6s. per share ...	10,368	18	0
Second Preference Shares—			
Balance of arrears of dividend to 30th June, 1890, 28s. 6d. per share.....	6,653	6	6
Dividend, 6 months to 31st Dec., 6s. per share...	1,400	14	0
Ordinary Shares—			
9d. per share (free of Income Tax)	3,312	0	9
Balance to current half-year's account	668	3	2
	£22,403	2	5

2. The traffic receipts for the six months show an increase of £1,608. 10s. 2d. as compared with the corresponding period.

3. The expenses of repairs to cables amount to £9,155, being £4,966 less than those for the corresponding six months.

4. Referring to the Directors' Report of the 23rd April, 1890, the result of the negotiations with the Colony of Martinique has been the acceptance by the Company of £500 in settlement of its claims.

5. The shareholders have already been informed that negotiations were pending for laying a new cable between Demerara and Trinidad. These negotiations have resulted in an Ordinance of the present year enacted by the Governor of British Guiana and the Court of Policy, by which an annual subsidy of £4,500 is payable to the Company during a period of 10 years, subject to the laying of a new cable between that colony and Trinidad, and the maintenance of telegraphic communication in terms of the said Ordinance. The Directors recommend that this cable should be laid in the course of this year, for which purpose, as also for the Barbados-St. Vincent cable laid in July last, a sum not exceeding £50,000 will be required, and as the existing £50,000 Five per Cent. Debentures fall due on the 31st December next the shareholders will be asked to empower the Board to borrow a sum of £100 000 and to issue Debentures or other securities at such times, with such security, and upon such terms as the Directors may think proper. The borrowing powers of the Board will thus be limited to the £100,000, which will be applied for the new cables and the payment at maturity of the £50,000 existing Debentures. Considering the loss sustained by the Company in the past from the suspension of subsidies, loss of traffic, the heavy expenses of forwarding messages during interruptions in the above sections, and the serious cost involved in urgent repairs, the Directors are of opinion that the telegraphing public, as well as all classes of the Company's shareholders, will be benefited by the proposed outlay.

6. It will be remembered that the original subsidy of £800 per annum granted by the colony of St. Vincent was in consequence of the severe commercial depression reduced in 1887 to £400 per annum. An improvement in the colony's finances having taken place the subsidy has now been increased to £600 per annum—a considerate recognition of the Company's need for support which the Directors have much satisfaction in acknowledging.

7. The s.s. "Duchesse of Marlborough" has been brought home for repairs. She arrived on the 4th instant, and on the completion of her repairs she will take out 70 knots of cable which is now being manufactured by Siemens Brothers and Co., Limited.

8. In accordance with the Articles of Association, Charles William Earle, Esq., and William Ford, Esq., retire at this meeting, and offer themselves for re-election. John George Griffiths, Esq., the Auditor, also retires, and offers himself for re-election.

Western Counties' and South Wales Telephone Company (Limited).

The following is the report of the Directors to be presented to the shareholders at the sixth annual ordinary general meeting of the Company, to be held at the Grand Hotel, Broad-street, Bristol, on Friday, the 15th day of May, 1891, at 2 p.m.:—

Capital Expenditure.—The capital expenditure for the year ending December 31, 1890, was £24,415. 15s. 6d., making a total of £164,409. 12s. 2d. to date.

Digitized by Google

Revenue.—The gross revenue of the Company for the year 1890 was £46,860. 15s., against £39,046. 19s. 6d. for the year ending December 31, 1889. The amount of income carried forward to next year's revenue, as representing sums received in advance for periods extending beyond December 31, 1890, is £14,212. 19s. 1d., against £12,292. 19s. brought in from the previous year.

Maintenance.—The whole of the Company's plant has been fully maintained and, where required, renewed out of the revenue. The Company have continued to substitute, at considerable expense, a large amount of copper and bronze wire for iron, which has increased the efficiency and durability of the plant.

Working Expenses.—The working expenses, including maintenance and all working charges for the year 1890, have been £13,775. 18s. 1d., against £11,936. 18s. 5d. for the year ended December 31, 1889.

Dividend.—Balance of net revenue account, £9,177. 7s. 3d.; dividend of 6 per cent. on the paid-up Preference share capital for the year ended December 31, 1890, £6,000; balance for appropriation, as per statement at end of accounts, £3,177. 7s. 3d.

The Directors recommend that the reserve fund, now standing at £1,700, be increased by the addition of £500; and that the balance, £2,677. 7s. 3d., be carried forward.

Growth of Business.—The number of subscribers to the exchange system and of private line renters has considerably increased, and the progress made during the year is considered to be most encouraging. The respective totals at the close of the years 1889 and 1890 were as follows:—

	Exchange.	Private.	Total.
December 31, 1890	2,875	712	3,587
December 31, 1889	2,392	671	3,063
Increase in 1890	483	41	524

Mileage of Trunk and Renters' Wires.—Erected up to December 31, 1890, 5,018 miles; erected up to December 31, 1889, 4,115 miles; increase representing new business during 1890, 903 miles. In addition to the above, 160 miles of wire have been renewed during the year.

Trunk Lines.—The Company has increased its trunk system, so that on December 31, 1890, it had 470 miles of trunk pole lines connecting towns with each other, carrying 2,182 miles of wire, against 383 miles of pole lines, carrying 1,804 miles of wire, at the corresponding date in the previous year. The continued rapid growth of the use of the Company's extensive system of trunk lines will be seen from the following figures:—

	Calls.
4 months ending December, 1887	27,338
12 " " 1888	142,443
12 " " 1889	184,754
12 " " 1890	249,160

Each call is answered, so that the number of communications has been double these figures. The foregoing figures form conclusive evidence of the increasing appreciation by subscribers and the public of the convenience and economy of telephonic intercommunication between towns, and represent a remarkable development of this branch of the Company's business.

London.—The Company has continued to keep in view the importance of connecting the principal towns of their district with the Metropolis, and arrangements with the National Telephone Company for the construction of a line putting Bristol and the south-western district and South Wales in direct communication with London have been frequently considered. It is also intended to connect Bournemouth, Southampton, and Portsmouth with London, *viâ* Winchester, Basingstoke, and Reading, when the necessary arrangements are completed.

Birmingham, Manchester, Liverpool.—Many inquiries having been received urging the importance of a connection with these great centres, trunk lines have been run between Gloucester, Worcester, and the boundary of the National and this Company's districts; thus that portion of this Company's extensive trunk line system, embracing Bristol, Bath, Gloucester, Newport, Cardiff, Swansea, &c., is now in communication with Birmingham, Liverpool, and Manchester, and the many other important towns connected therewith in the North and Midland district.

Public Call Rooms and Trunk Toll Messages.—Additional call rooms for the use of subscribers and the public have been opened during the year in the various towns, where, on payment of 2d., the Company's local exchange subscribers may be spoken with; or, on payment of a small toll, according to distance, any person can speak to any town connected by trunk lines; the Company's subscribers and their representatives having the important advantage of the free use of all call rooms in any town in the Company's district where they may happen to be, for local communication with other subscribers in that town.

Ladies' Free Call Room Passes.—A further and novel extension of call room facilities has just been made by the Company issuing a complimentary call room pass for use by the lady members of subscribers' families available for local calls made by the bearer in any town in the Company's district where there is a call room. The convenience of the telephone to ladies when in the neighbourhood of any of the Company's numerous call rooms will not fail to be appreciated, while at the same time the Company will gain advantage by making their extensive system of telephone exchanges better known and increasingly popular.

The Post Office.—The Directors have pleasure in acknowledging the uniform courtesy of the permanent officials of the Post Office department.

Retiring Directors and Auditors.—Mr. Charles Nash and Mr. Richard Cory retire by rotation, but are eligible for re-election. Messrs. Hudson Smith, Briggs and Co. retire, but are eligible for re-election.

NEW COMPANIES REGISTERED.

ARMSTRONG'S GLASS COMPANY (LIMITED).—Registered with a capital of £10,000 in £10 shares. Object: To carry into effect an agreement expressed to be made between John Armstrong of the one part and the company of the other part, for the purchase of certain patent rights and inventions, and to carry on, at Albion, Staffordshire, and elsewhere, the business of glass manufacturing in all its branches.

BRITISH ELECTROLYTIC SYNDICATE (LIMITED).—Registered by Alfred Wells, 27, Chancery-lane, W.C., with a capital of £100,000 in £1 shares. To carry into effect an agreement expressed to be made between Frederick Bennett of the one part and the Company of the other part, and to carry on generally the business of miners, metallurgists, and smelters. The first subscribers are:—F. Safford, 2, Garden-court, Temple, E.C.; T. Lewis, Bryn Ogwen, Bangor; W. J. Tippetts, 11, Maiden-lane, Queen-street, E.C.; A. McLaren, 42, Newsome-street, Cootham, Redcar; H. T. Middleton, 8, Princes-street, Westminster, S.W.; A. C. Hutchins, Drayton Lodge, Ealing Dean, W.; A. J. Jordan, Keymer Vale, Keymer, Sussex. There shall not be less than three nor more than seven Directors; the first shall be appointed by the subscribers to the Memorandum of Association. Qualification, £100. Remuneration, £1,000, with a further 5 per cent after 15 per cent. dividend.

ELECTRICAL ADVERTISING SYNDICATE (LIMITED).—Registered with a capital of £10,000 in £10 shares. Object: To acquire certain patents relating to the application of electrical energy to the purposes of advertisements and to develop the same.

T. L. HEMMING AND CO. (LIMITED).—Registered with a capital of £5,000 in £10 shares. Object: The acquisition of the business of an electrical and general engineer, now carried on by Thomas Lynch Hemming, John Thornton and Thomas Richard Canning, trading as T. L. Hemming and Co., at 96 New John-street West, Birmingham, and to develop and extend the same.

NEW COMPANIES IN APRIL.—The total number of new companies registered at Somerset House in April was 230, with a total capital of £17,676,558, of which amount, according to the *Financial Times*, electricity in its various uses was responsible for £302,000, and engineering and general metal working for £433,000.

ARTHUR D. STUDD AND CO. (LIMITED).—Registered with a capital of £8,000 in £5 shares. Object: To acquire the business of an engineer and ironfounder now carried on by A. D. Studd, at Kettering.

WHESSOE FOUNDRY COMPANY (LIMITED).—Registered by Andrew Mellor and Smith, 27, Clement's-lane, E.C., with a capital of £50,000 in £10 shares. Object: To acquire the undertaking heretofore carried on under the style of the owners of the Whessoe Foundry, at Darlington, Yorkshire, and to carry on generally the business of mechanical, electrical, and consulting engineers, &c.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the past week amounted to £5,444.

CITY AND SOUTH LONDON RAILWAY COMPANY.—The traffic receipts of this Company for the week ended May 3rd amounted to £733.

CONSOLIDATED TELEPHONE CONSTRUCTION AND MAINTENANCE COMPANY.—The Directors of this Company recommend dividends at the rate of 6 per cent. on the preference shares and 7 per cent. on the ordinary shares, less income-tax, making 6 per cent. per annum on both descriptions of shares for the year ending March 31st.

CUBA SUBMARINE TELEGRAPH COMPANY.—The estimated traffic receipts of this Company for the month of April were £3,700, as compared with £3,624 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY.—The traffic receipts of this Company for the month of April, 1891, amounted to £1,825, as against £2,089 in the corresponding period of last year, or a decrease of £264.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this Company for April were £60,909, as against £55,042 for the same period of 1890 an increase of £5,867.

EASTERN EXTENSION TELEGRAPH COMPANY.—The receipts of this Company for April amounted to £44,729, as against £40,696 in the corresponding period, showing an increase of £4,033.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this Company are as follows:—Receipts in April, 1891, £23,600; 1st January to 31st April, 1891, £88,000; corresponding months, 18.0, £81,800; corresponding months, 1889, £84,000.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts o this Company for the two weeks ended April 30th show a decrease of £712 as compared with the corresponding period.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended May 1, 1891, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,363.

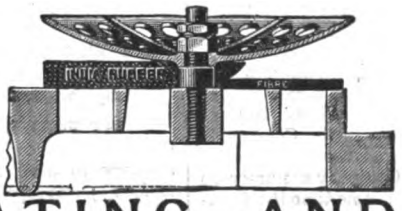
NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept. 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 678.—Vol. XXVII. FRIDAY, MAY 15, 1891. Price Fourpence.

NOTES.

The meeting of the Physical Society, at Cambridge, on Saturday last, was a brilliant innovation on the ordinary, sometimes very ordinary, meetings at South Kensington. About 100 members and visitors left by the 11 a.m. express, and on arriving at Cambridge became the guests of the Cambridge members, and proceeded to Emmanuel College. After a stroll in the Fellows' garden, they were entertained at lunch in the college hall, under the presidency of Mr. W. N. Shaw. A meeting of the Society was held in the lecture room of the Cavendish Laboratory. Prof. J. J. Thomson had the temerity to offer some very interesting experiments, which depended on the action of an influence machine. The rehearsal, a few minutes before the meeting, had gone off excellently, as rehearsals do, but on attempting to repeat them before the audience the machine stubbornly refused, as influence machines do, to yield a spark, notwithstanding the presence of Mr. Wimshurst and Dr. Oliver Lodge. The application of warm blankets and other restoratives subsequently brought it round, and the experiments, which duly "went off," will be reported in our columns next week.

After the meeting, the visitors inspected the Cavendish and other laboratories. "The Cavendish" was not in its usual working condition, for a number of the historical relics and portions of apparatus used by Maxwell were displayed for the occasion; many of these were easily recognised by the visitors from the illustrations of them in his works. The requirements and the function of the Cavendish Laboratory differ very widely from those of the Technical Colleges, and we understand that some of the members who are connected with these institutions were struck with the large amount of valuable apparatus in the cupboards besides that in use and out on show for the occasion. They noticed that, except for elementary work, little or no apparatus was permanently fitted up for rapid measurement with a fair degree of accuracy, the fact being that the line between elementary work and research is very sharply drawn. The excellent text-book on Practical Physics by Glazebrook and Shaw gives a fair notion of the students' course, and the principle of encouraging them to acquire a working knowledge through a considerable range and variety of branches, rather than to spend all their time in carrying out a few elaborate measurements.

In the private rooms were shown, among other things, the 50-foot vacuum tube used by Prof. J. J. Thomson in his recent research, alluded to on page 658 of our last volume; while Mr. Shaw exhibited his ingenious adaptation of the principle of the Wheatstone bridge to the measurement of the friction of air in passing through various orifices and tubes, thus resuscitating the well-nigh extinct science of Pneumatics. The "Warden of the Ohm" showed his spectrophotometer, some new Clark cells, and various resistance standards, both ancient and modern; and, in the room which was once occupied by Maxwell, the Cambridge Scientific Instrument Company, represented by Mr. Horace Darwin, exhibited numerous specimens of their work, including a dividing engine, Boy's radio-micrometer, and several different kinds of recording instruments, one of which, intended for registering the growth of plants, was engaged in recording the loss of weight of a burning candle.

Mr. Vignoles' Paper, which we print in this issue, contains an account of the magnetic researches carried out by the writer, in conjunction with Mr. Evershed. It forms an excellent summary of the principal facts known about commercial specimens of iron, and, while necessarily describing much that is well known, presents several novel features. The experiments differ from those of Prof. Ewing in that they were carried out in the shops, and not in the laboratory; closed rings of iron were used instead of long bars, and the masses of iron dealt with were considerably greater. The method of test also seems a distinct improvement on that of Prof. Ewing, and, as Prof. Ayrton suggested, it could have been still further improved if the two magnetising coils, instead of being separate, had been wound over the same part of the ring. The results, moreover, could have been more confidently applied to transformers if an additional coil, doubly wound like an ordinary resistance coil, had been wound round the ring and subjected to the passage of a strong current. The opposing magnetising effects of the two parts of this coil would have produced magnetic leakage, such as is caused in a transformer, owing to the action of the primary and secondary currents, and probably the permeability and hysteresis curves would be similarly affected in the two cases. The Paper was followed by an unusually vigorous and critical discussion, which we hope to publish next week.

The train-lighting dynamo which we describe this week appears at first sight to be needlessly complicated. That the

Digitized by Google

details should be more intricate than is usual in modern dynamos is to be expected, since the conditions under which it is used are peculiar; but it is found to work well, and additional trains are being fitted according to the system described by Mr. LANGDON at the Institution of Civil Engineers last week. On several lines it has been found impossible to give proper care and attention to steam dynamos mounted on the engine, and in attempting to drive from the axle many difficulties present themselves. Accumulators must be used, and while these may be a blessing to a central station engineer, they are generally found to be a nuisance by most other persons, and under the difficult conditions of railway work have severely taxed the patience of those who have had to deal with them.

SUCH trains as those which run on the Brighton line are, of course, quite easy to light by electricity, but where stoppages are frequent, and, above all, where the train is separated into different portions, the problem is no simple one. It was the latter difficulty which proved too much for the axle-driven system, tried on the Lancashire and Yorkshire Railway in 1885. The reversing switch and some other details were the same as those on the HOLMES dynamo, but it was found necessary to begin to charge at about 18 miles an hour, or there would not have been time during the day to charge the batteries. It is here where express trains have an advantage over slow or stopping trains which cannot be lit by axle driving. While alluding to this experiment in 1885 we take the opportunity of remarking that wire gauze brushes cut "on the bias" were used. They were rolled up, to the size and shape of cigarettes, and each one was pushed up to its work by a spiral spring. They were set square against the commutator, which ran in either direction. They are not claimed in the patent, and are therefore not patentable.

THE insecurity of lead-covered wire under certain conditions is strikingly exemplified by some seriously corroded specimens which have been sent to us by Sir DAVID SALOMONS. He informs us that the wire is of Swiss manufacture, and that it was laid on wood in a thoroughly dry place about four years ago. In reply to our inquiries we learn that it was run between the ceiling and floor, resting on the laths at places, and here and there on yellow deal. The wire is about No. 22 S.W.G., and is covered to about 115 mils with a fibre resembling jute impregnated with Stockholm tar. Over this is a thin and apparently irregular covering of lead varying from 15 to 20 mils in thickness, bringing the exterior diameter up to about No. 8 B.W.G. The lead is partially converted into sulphate or carbonate, and is quite corroded away in patches of an inch or so, leaving the tarred fibre bare. The insulation, such as it is, which is afforded by the fibre does not seem to be affected, but, deprived of the protection of the lead, it is less serviceable than the "tape and tar" which was occasionally used eight or nine years ago. The lead, judging by its softness, appears to be pure.

IT is well known among architects that pure lead in contact with calic sulphate will be corroded, and that in contact with oak it will be attacked by the acetic acid present, and will be converted into white lead by carbonic acid. There is a temptation to use lead where the drawing on process of covering conductors is employed, and care should be taken to employ a suitable alloy. Mr. PREECE, in the Paper read before the Institution of Electrical Engineers, advocated the use of lead, and remarked that the lead pipes used by the Romans were still visible at Pompeii; adding that, when properly protected, lead ought to last for centuries. But the Romans did not trouble to extract the tin, antimony, and silver which exist in the crude metal, and it is probable that it is only when it is properly *alloyed* that "lead" will last for centuries.

THE arrangement of the Science Collection at South Kensington has many present inconveniences, and some of these it will be impossible to remedy if the new picture gallery be planted on the very spot where extension of the science schools could best be made. The largest Wimshurst machine in existence, which was presented by the inventor, can never be used for teaching purposes, since it is deposited upstairs, a quarter of a mile away from the lecture room, and is, of course, far too heavy to move about.

Metz.—The Metz Gas Company has arranged with the town authorities to establish an electric lighting central station, the motive power being obtained from the Moselle.

Obituary.—The death is announced, on Monday last, of M. Edmond Becquerel, who died in Paris, at the age of 71. We hope to give a full obituary notice of this distinguished *savant* in our next issue.

Electricity at the Chicago Auditorium.—There are 230 miles of electric wire and cables in this building. Current is supplied to 10,000 lamps and for other purposes by 11 dynamos, and 13 electric motors are used for driving fans.

Hampstead Vestry.—At a special meeting of this Vestry, last week, it was decided, after considerable discussion, to prepare a draft Provisional Order, and to inform the Board of Trade of the Vestry's decision. Mr. Preece attended and gave evidence.

Royal Society.—Among the Papers down for reading before the Royal Society, yesterday, was one by Captain Abney on "The Limit of Visibility of the Different Rays of the Spectrum. Preliminary Note," and another by Mr. J. Larmor, "On the Theory of Electro-dynamics."

Institution of Electrical Engineers.—A general meeting of the students of the Institution was held on Friday, May 8th, when a Paper was read on "Magnetism" by Mr. C. O. Lloyd. The next meeting will take place on Friday, May 22nd, when Messrs. Haig and Griffin will read a Paper on "Arc Lamps."

Boilers.—The experimental section of the Magdeburg society of boiler users communicates the fact that ordinary cement made into a stiff paste with water (so that it adheres to a vertical wall) is admirably adapted for closing the manholes of boilers, and holds the two surfaces well together. The cement becomes sufficiently hard in 8-12 hours, and can then be submitted to pressure.

Transmission of Power by the Rotating Current.—Schuckert and Co., of Nürnberg, who have for the past three years been carrying out experiments with the so-called rotating current field motors, have completed an installation for the transmission of 250 H.P. at Luisenthal, near Gmund. Of the total amount, 200 H.P. are transmitted by means of the rotating current.

Provisional Orders.—Another batch of Provisional Orders has been granted by the Board of Trade relating to Bromley (Kent), Preston, Scarborough, Torquay, Tunbridge Wells, Withington District, Edinburgh, Paisley, Hertford, Killarney,

Digitized by Google

Kingston-upon-Thames, Liverpool, Toxteth Park, Whitehaven, Birmingham, Cardiff, Exeter, Ipswich, Whitby, Camberwell, Islington, Southwark, Wandsworth District, Westminster, City of London, Clerkenwell, Chelsea, Woolwich, Newport (Mon.), Poole, and Weybridge.

The Sims-Edison Torpedo.—The First Lord of the Admiralty was asked, last week, whether his attention had been called to the public trial of the Sims-Edison torpedo made at Havre, and whether he intended having experiments made with it at Portsmouth or elsewhere. It was stated in reply that no experiments would be carried out by the Admiralty, but that the trials had been attended by officers acquainted with the Brennan torpedo, and its capabilities, in comparison with that weapon, would doubtless be reported on and considered.

Telephone Trunk Wire Extensions in Scandinavia.—According to the *Elektrotechnische Zeitschrift*, Christiania and Stockholm, which are some 275 miles apart, are to be placed in telephonic connection. In Norway the line goes from Christiania to the border at Magnor. In Sweden the Stockholm-Orebro-Carlstad line will be used, the necessary extensions being made. This will place Christiania in communication with several towns in Central Sweden. For several hours each day the line will be reserved exclusively for speech between the two capitals.

German Electric Lighting Statistics.—From an inquiry instituted by the Government Department concerned with the telegraph and telephone services, it appears that there existed in the German Empire (exclusive of Wurtemberg and Bavaria) on January 1, 1890, 2,590 electric-light installations, comprising 339,000 incandescent lamps and 2,160 arc lamps. There were also nine installations connected with the electrolytic industry and 16 transmission of power plants. Some 86 per cent. of the lighting installations were supplied with continuous currents, 9 per cent. employed alternating currents, and 5 per cent. employed both.

Frankfort Exhibition.—The Grand Duke of Weimar has lent the Exhibition authorities the electric machine with which Goethe made his experiments, and which is included in the relics in the Goethe Museum at Weimar. The Congress of German Municipal Authorities, to be convened by the chief magistrate of Frankfort during the Exhibition, is to be held on August 27th, 28th, and 29th. The two electrical boats which will be on the Main during the Exhibition are to be accompanied by a boat propelled by a petroleum engine. The engine will also drive a small dynamo which will generate current for the lights.

Electric Traction on the West Metropolitan Tramways.—A Select Committee of the House of Commons passed a Bill on Wednesday extending the time for the completion of the West Metropolitan Tramways in Hammersmith, Chiswick, Acton, and Ealing, to August next year, and also obtaining powers to work the line by electricity. The only petitioners against the measure were the National Telephone Company, who, supported by the evidence of Sir William Thomson and Sir Frederick Bramwell, succeeded in obtaining the insertion of a clause compelling the tramway company to insulate their wires in such a way as not to interfere with the working of the telephone system.

The Electric Lighting of Westminster Hall.—Mr. Story-Maskelyne asked the First Commissioner of Works, last week, whether, considering the deleterious effect of the acid products of the combustion of gas on the ancient wooden roof of Westminster Hall, he would consider the advisability of substituting the electric light for the gaslights at present employed. It was stated in reply that the matter had been carefully inquired into, and that it had been found that at one spot the hammer beams in the roof of Westminster Hall had been blackened, though not charred, by gas lamps, which are placed some 15ft. or 20ft. below them. There was no ground for believing that any permanent injury had been done. Gas was being replaced by electricity throughout the Palace generally as rapidly as possible.

An Electric Crane.—An electric hoisting and conveying machine has recently come into operation at Cleveland, Ohio, and has been examined by prominent iron ore and coal shippers, and pronounced a success. A 30 H.P. electric motor is mounted upon a light tramcar holding suitable hoisting mechanism, and the operator riding on this car hoists the load from any desired point and rapidly conveys it to the place of unloading. The constant presence of the operator over his work has a great advantage over steam automatic cable systems in present use. The present work performed by the plant is unloading a vessel of iron ore, hoisting a load of 3,000lb. vertically 5ft. per second, then travelling across a bridge 30ft. high and 200ft. long, spanning the ore dock, the cross travel being made in 10secs., and the operator stopping the car, holding the bucket, and dumping the load at any desired point.

Hydrochloric Acid in Bichromate Cells.—Mr. Charles Steinmetz writes to the *Electrical Engineer* of New York to the effect that he has found a mixture of bichromate, sulphuric acid, and crude muriatic (hydrochloric) acid to be an excellent solution for use in the bichromate battery. After over half a day's continuous use with a very low external resistance, neither the E.M.F. nor the internal resistance was perceptibly changed. None of the cells got hot; neither was there any boiling over or formation of crystals on the zinc, but the battery ran steadily until the liquid showed the greenish-yellow colour of approaching exhaustion. In a subsequent issue, however, Mr. Charles J. Reed points out that the only advantage that can result from the use of hydrochloric acid is the evolution of chlorine at the expense of the chromic acid. The advantage of free chlorine in a battery seems to him doubtful, and its preparation by the action of a chromate on a chloride to be, at least, expensive.

Transmission of Power Plants by the Oerlikon Works.—The *Elektrotechnischer Anzeiger* gives the following list of power installations carried out by the Oerlikon Works:—

Place.	Horse-power transmitted.	Distance in miles.	Efficiency. Per cent.
Solothurn	50	5·0	75
Derenduigen	280	·8	80
Lugano	60	5·0	—
Bregenz	200	1·6	78
Schio	300	3·7	73
Lucerne	120	1·9	70
Schaffhausen	600	·4	75
Styrermühl	360	·4	80
Kematen	125	1·6	78
Mendoza.....	480	1·9	75

—	320	1·9	75

Overhead Wires at Sheffield.—Major Cardew has made a lengthy report with reference to the electric light overhead wires, and a copy of it has been forwarded to the Parliamentary Powers Committee of the Sheffield Corporation. Major Cardew reports that the insulation is dangerously insufficient, and he considers it utterly untrustworthy. A good system of testing is in use, and when the insulation shows any unusual leakage prompt steps are taken to remedy it. The careful system of testing and maintenance considerably diminishes the risks, but he cannot view the use of such wire in a crowded town without apprehension. The Parliamentary Powers Committee, on the receipt of this report, instructed the Town Clerk to write to the Sheffield Telephone Exchange and Electric Light Company, and inquire what they were doing with regard to matters mentioned in the report. They also passed a resolution expressing the opinion that it was desirable that all wires for the supply of electric light should be carried underground.

Faults on a Subterranean Telegraph Line.—In a recent number of the *Annales Télégraphiques*, M. Brylinski gives some particulars with regard to the extraordinarily faulty condition of the Tarare-Roanne section of the subterranean telegraph line running from Lyons to La Palisse, a distance of some 70 miles. The two end sections of the line consist of insulated cables run in cast-iron pipes, and these are in excellent condition. On the central or Tarare-Roanne section, 26 miles long, however, 394 faults were located, or over 15 per mile. This section was laid down in 1885, and consists of gutta-percha

Digitized by Google

insulated cables run in cement conduits. Whole lengths of the outer insulation were found in a state of putrid decomposition, the braiding and taping had entirely disappeared, and the conduit was filled with a black pulp. The bare cores were covered with long yellowish-grey streaks, and it seems probable that these were patches of cement deposited on the gutta-percha by the water which is always to be found in the conduit. At these spots the gutta-percha was spongy and eroded.

Boilers Registration Bill.—The Engineering Trade Section of the London Chamber of Commerce at their meeting, held on April 22, 1891, after considering the provisions of this Bill, adopted the appended memorandum embodying the conditions which they consider should be observed in any legislation affecting the registration of boilers and designed to reduce the number of explosions arising from various causes. The Committee were of opinion that the Bill, if amended in accordance with their suggestions, would better effect the object which its promoters have in view. *Memorandum.*—1. That every boiler owner shall register his boiler or boilers at the Board of Trade, with particulars (as per the schedule to the Bill) of every boiler owned by him, together with full data and the name of his engineer or other person directly responsible for the condition and management of the boiler or boilers. 2. That the Board of Trade shall keep a register of all boilers and their owners and of the managers responsible for the same, and shall take proceedings against boiler owners who neglect to have them registered in due course. 3. That the Board of Trade may cause an examination to be made in the case of all explosions, and shall make such an examination in every case where explosion causes damage externally to the boiler or injury to life or limb, or both, and the Board of Trade shall prosecute the party or parties whom they consider to blame. 4. That the boiler owner shall pay a small fee to the Board of Trade to meet the expenses of registration and prosecution.

The Giraud Thermo-Electric Stove.—The process of transforming the thermic energy of combustion into electric energy actually and generally employed is certainly by far the most complicated of any, for it necessitates a passage through the intermediary of mechanical work; but it is undoubtedly the most economical in the actual state of science, and all efforts hitherto made to replace it have failed, owing to the low efficiency of the transforming apparatus, the thermopile. In fact, the most perfect thermopiles consume 30 litres (1.05 cubic feet) of lighting gas per watt-hour, or 30 cubic metres (1,050 cubic feet) per kilowatt-hour, which makes the price of electrical energy absolutely prohibitory from the commercial and even domestic point of view. The coefficient of transformation is less than five in a thousand, that is to say, less than one-half per cent. of the thermic energy of combustion is delivered to the external circuit available for use. But the problem, says M. Hospitalier in *Le Génie Civil*, completely changes its aspect if, instead of considering the electrical energy as the principal product of combustion, we consider it as an accessory or secondary product, the principal one being the heat which we can use in its integrity, with the exception of a few thousandths, in spite of the accessory product. From this point of view, M. Hospitalier is sanguine enough to think that something may be expected from the thermo-electric stove of Dr. Giraud, of Chantilly. This gives 30 or 40 watts permanently and regularly when consuming its usual quantity of combustible. The 800 to 1,000 watt-hours produced daily by the apparatus and stored in accumulators would enable one to run some 25 10 c.-p. lamps. The idea, therefore, deserves attention and investigation, thinks M. Hospitalier.

New Edison Central Station Plant.—The Edison Company of America are building a line of triple expansion engines coupled direct to multipolar dynamos, a machine being attached to either end of the main crank shaft. The steam pressure employed is 160lb. The generators mostly have 6 to 10 poles, with a ring armature revolving within a concentric circular field-magnet frame with internally projecting pole pieces. The frame of the field-magnet consists of a single casting. The Gramme ring type of winding is employed, but, instead of using coils of a number of convolutions connected to each segment of the commutator, each convolution is connected directly with the commutator bar. For this purpose bare U-shape copper strips are slipped over one side of the core, insulated from one another, and each succeeding U-shaped bar of this character is connected direct to a commutator bar. The brushes bear upon the commutator in a vertical plane. This construction with bare conductors is permissible on account of the very small difference of potential, 1¼ volt existing between each bar. The number of bars employed in this type of machine is 944. Each bar is, therefore, equivalent to a coil of the usual type of Gramme winding; but the absence of contiguous layers entirely avoids self-induction, and hence sparking, the machine operating without the slightest indication of such a disturbance. Several brushes are employed, which can be shifted simultaneously by means of a hand-wheel, and which can also be lifted at once from the surface of the commutator. This type of combined engine and dynamo, says the *Electrical Engineer* of New York, will probably be employed in the new Edison station in New York, where no less than fourteen 2-400 kilowatt generators will be placed. In the same way the Cincinnati station will be equipped with ten 2-400 kilowatt generators.

Royal Society Candidates.—Fifteen candidates were selected on April 30th by the Council of the Royal Society, to be recommended for election into the Society. The ballot will take place on June 4th. The work of the three following candidates has been mainly of electrical interest, and some of the statements of qualifications may be of interest.—Oliver Heaviside. Has applied higher mathematics with power and success to the developments of Maxwell's theory of electro-magnetic wave propagation, and has extended our knowledge of facts and principles in several directions and into great detail. He is the author of the following Papers among many others:—"On Electro-magnetic Induction and its Propagation" (48 parts, 1885-87, in *The Electrician*); "The Induction of Currents in Cores" (15 parts, 1884-85); "Some Electrostatic and Magnetic Problems" (5 parts, 1883); "Current Energy" (19 parts, 1883-84); "On the Electro-magnetic Effects due to the Motion of Electrification through a Dielectric" (*Phil. Mag.*, 1889); "The General Solution of Maxwell's Equations" (*Phil. Mag.*); "On Electro-magnetic Waves" (6 parts, *Phil. Mag.*, 1888); "On Resistance and Conductance Operators" (*Phil. Mag.*, 1887); "On the Self-induction of Wires" (7 parts, *Phil. Mag.*, 1886-87); "On the Electro-magnetic Wave Surface" (*Phil. Mag.*, 1885); "On the Electro-magnetic Effect of a Moving Charge;" "The Deflection of an Electro-magnetic Wave by Motion of the Medium;" "On the Working of Cells with Condensers" (*Phil. Mag.*, 1874); "On the Extra Current" (1876); "On the Speed of Signalling through Heterogeneous Telegraph Circuits" (*ibid.*, 1877); "On the Effect of Faults on the Speed of Working Cables;" "On Electro-magnets" (*Jour.* Soc. Tel. Eng.); "On Induction between Parallel Wires" (*ibid.*)—W. N. Shaw, Demonstrator of Physics in the Cavendish Laboratory at Cambridge from 1880 to 1887, and now University Lecturer in Physics, bore an important part in the organisation of the laboratory. A considerable part of the success of the Cambridge School of Physics is due to his exertions. Author of numerous Books and Papers.—Silvanus P. Thompson, Principal and Professor of Physics in the City and Guilds of London Technical College, Finsbury; formerly Professor of Experimental Physics in University College, Bristol. Author of many Papers, including the following:—"The Theory of the Magnetic Balance" (*Proc.* Roy. Soc., 1884); "Electro-deposition of Alloys" (*ibid.*, 1887); "Subjective Interference of Sound" (*Phil. Mag.*, 1887); "Opacity of Tourmaline Crystals" (*ibid.*, 1881); "The Meaning of the Constant in Bernouilli's Law of the Lifting Power of Magnets" (*Phil. Mag.*, 1888); "Development of the Mercurial Air Pump" (*Jour.* Soc. Arts, 1887); "The Influence Machine from 1788 to 1888" (*Jour.* Soc. Telegr. Engin., 1888). Author of a treatise on "Dynamo-Electric Machinery" (3rd edit., 1888), and of an elementary text-book of Electricity and Magnetism (43rd thousand, 1889), which has gone through many English and several foreign editions. Originator of improvements in polarising prisms, in the method of adjusting resistance coils, and in sundry electrical apparatus. Distinguished for his acquaintance with the science of electricity, more particularly in its experimental and technical aspects.

EXPERIMENTS ON THE RATIO OF ELECTROSTATIC TO ELECTRO-MAGNETIC INDUCTIVE DISTURBANCE BETWEEN NEIGHBOURING TELEPHONE CIRCUITS.

BY A. E. KENNELLY.

The following experiments were made with the object of not only verifying the experimental results obtained by Mr. J. J. Carty, as stated in his recent interesting paper "On Inductive Disturbances in Telephone Circuits,"* read before the American Institute of Electrical Engineers, but also to check within fair quantitative limits the deductions from those results by reference to theory.

It would seem that both these aims have been reasonably fulfilled. Some 305 metres (1,000ft.) of double conductor, gutta-percha cable of dimensions shown in the diagram, were

FIG. 1.

" " outer " 0·5 ω " " "

laid out on the ground in a figure roughly representing a complete rectangle of sides 30, and 120 metres in length. The cable thus afforded two complete and independent circuits by the interior and exterior copper strands, the insulation between which was 20,000 megohms at the end of one minute, and their mutual electrostatic capacity 0·075 microfarad, from measurements taken at the time. The insulation of the outer strand to ground was about 4,000 megohms. The interior conductor was used as the primary or inducing circuit, and the exterior conductor as the secondary or recipient circuit. The transmitter or source of disturbance was a continuous current dynamo giving 125 volts as its terminals (shunt wound), supplying about 50 amperes to incandescent lamps, and with one side grounded. A simple harmonic variation of electromotive force would, of course, be preferable for quantitative measurements, but there is some experimental difficulty in creating such a variation having the necessary frequency, while if the pure sine wave of disturbance is relinquished, and the exact shape of the wave is neglected, a dynamo becomes a

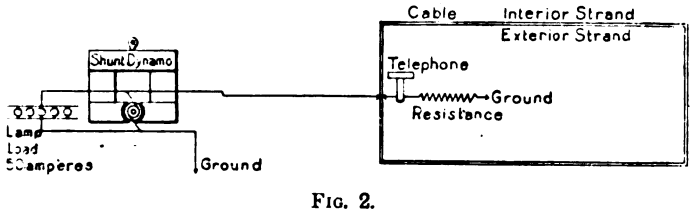

FIG. 2.

very convenient transmitter. The small fluctuations in its E.M.F. produced by the successive reversal towards the external circuit of each armature coil as it passes under the brushes, are periodic variations whose frequency will be equal to the number of bars passing under each brush per second; and, conversely, it is only necessary to join a telephone across the mains of a continuous current circuit (through protecting resistance of say 10,000 ω), to hear a note in the telephone† whose frequency corresponds to the number of commutator bars passed over in one second by one brush. A trained musical ear will often identify this note, and thus the frequency, very closely, and the principle may be practically useful for distinguishing circuits operating at the same continuous presure, but served by generators of different type, or to ascertain the speed of the dynamo armature when the number of its commutator bars is known. In this instance, the telephone note was identified by the use of Helmholtz resonators as nearest to c''' of 1,300 ∿. By measuring the revolution speed of the armature, the number of bars passing under the brush per second was 1,257. This number was, therefore, taken as the frequency of the periodic disturbance in these experiments. Various combinations of the two cable circuits were tried, so as to obtain electrostatic induction only, electromagnetic induction only, or both together. Of these the two most important cases bearing on the question are shown in the accompanying diagrams. Fig. 2 shows the arrangement of circuits in which electrostatic action is almost wholly active, and Fig. 3 the case in which electrostatic induction is negligible, electro-magnetic induction being displayed to fullest advantage.

Referring to Fig. 2, the dynamo is connected directly to the interior conductor, while the exterior is connected to ground through a Bell telephone having a resistance of 73 ohm, and an inductance of 113 *h*. The dynamo note was heard in this telephone. The effect was not due to leakage, because a battery of 50 volts replacing the dynamo, and working through an interruptor, produced no sound. The disturbance was, therefore, accepted as wholly electrostatic. It required a very large resistance in circuit between the telephone and ground to bring the note down to the limit of audibility. With resistances of graphite, the amount needed to reach this limit was found to lie between 2 megohms and 10 megohms. It was estimated at 7 megohms.

In Fig. 3, the dynamo is shown connected through a galvanometer and bank of lamps to the interior conductor of the cable, the other end of which is grounded. The only appreciable inductance in this primary circuit is in the dynamo

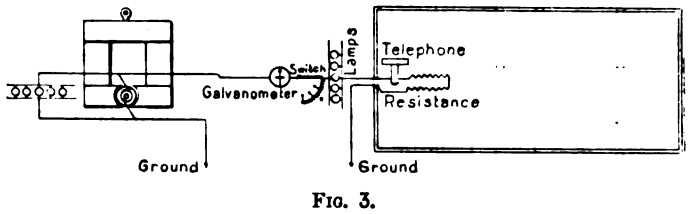

FIG. 3.

armature. Inductance is capable of being inserted between the galvanometer and lamps at will. The outside conductor completes its own circuit, insulated from the ground, through the telephone and resistance. Corresponding to different strengths of current in the primary circuit, resistance is added in the secondary circuit to bring the sound in the telephone down to the limit of audibility.

The results are given in the following table :—

Current in primary circuit.	Resistance in primary circuit.	Inductance added to primary circuit.	Impedance in primary circuit.	Resistance in secondary circuit.	Inductance in secondary circuit.	Impedance in secondary circuit.	$\omega_1\ \omega_2$
Amperes.	Ohms.	Millihenrys	Ohms.	Ohms.	Millihenrys.	Ohms.	(Ohms².)
0·522	239·7	—	240	80,000	113	80,000	$1·92 \times 10^7$
0·742	169	—	169	110,000	,,	110,000	$1·86 \times 10^7$
1·419	88	—	88	200,000	,,	200,000	$1·76 \times 10^7$
2·608	47·9	—	47·9	400,000	,,	400,000	$1·92 \times 10^7$
2·774	45·1	4·96	59·7	110,000	,,	110,000	$6·57 \times 10^6$
2·868	43·6	37·9	302·5	20,000	,,	20,000	$6·05 \times 10^6$
2·608	47·9	0	47·9	400,000	,,	400,000	$1·92 \times 10^7$

The first column gives the observed steady currents in the primary circuit, from which, since the pressure was 125 volts, the resistances in the second column are found. The third column gives the inductance (in coreless coils of copper wire) added to the primary circuit, and from these, with a frequency of 1257 ∿, the impedance inserted in the primary circuit to the variations of its E.M.F. are given in column 4. In No. 5 appear the resistances added to the secondary circuit in order to quench the dynamo note in the telephone; and since the only appreciable inductance in the secondary circuit was that of the telephone, negligible in series with the large resistances, the impedances of column 7 are only repetitions of these re-

* See *The Electrician*, Vol. XXVI., April 10, p. 705.

† An arc lamp will sometimes emit the same note apparently from its "crater."

Digitized by Google

sistances. The last column gives the product of the primary and secondary impedances. This value is nearly uniform except for the cases in which inductance is added to the primary circuit. The marked discrepancy in these two cases is, perhaps, due to the shunting action of the load circuit supplied by the dynamo, which, being nearly inductanceless, would reduce the periodic current in the primary circuit below the calculated amount, in about the ratio here represented. For the same reason the inductance of the dynamo armature (about 0·3 h) has not been taken into account. It appears, however, probable from an inspection of the results, that with a resistance of 7 megohms in the secondary circuit, it would be necessary to reduce the primary circuit resistance to about 3 ohms., in order to just render the dynamo note audible in the telephone. The dynamo in these experiments was at a distance of about 250ft. from the telephone, and silence was obtained in every experiment as soon as the wires leading to the dynamo were disconnected from the primary circuit.

We may now check these results by calculation. The check can only be a rough one, because we shall have to assume that the periodic variation of E.M.F. is a simple harmonic function of time, and that the inductance of the dynamo armature is negligible.

Let e be the E.M.F. generated by the dynamo at any instant.
" K " " mutual electrostatic capacity of the two circuits.
" M " " mutual electro-magnetic capacity of the two circuits.
" p " " pulsation of the periodic variation of E.M.F. $(2\pi n)$, $n = 1257$.
" γ_c " " current in the secondary circuit at any instant in Fig. 2.
" γ_m " " current in the secondary circuit at any instant in Fig. 3.
" ω_1 " " impedance of the primary circuit.
" ω_2 " " impedance of the secondary circuit.
" r_2 " " resistance of the secondary circuit.

All expressed in Absolute El. Mag. Units.

Then in Fig. 2 :—If no resistance existed in the secondary path to ground, we should have

$$\gamma_c = -K\frac{de}{dt} = -pKE\cos pt \quad . \quad . \quad . \quad (1),$$

where E is the maximum ± periodic variation of e, but with resistance r_2 inserted as shown, the current becomes very nearly

$$\gamma_c = -\frac{E}{r_2}\cos pt \quad . \quad . \quad . \quad . \quad . \quad . \quad (2).$$

In the case represented by Fig. 3, we have

$$\gamma_m = -\frac{de}{dt}\frac{M}{\omega_1\omega_2} = -\frac{pME\cos pt}{\omega_1\omega_2} \quad . \quad . \quad (3),$$

and

$$\frac{\gamma_c}{\gamma_m} = \frac{\omega_1\omega_2}{pr_2M} \quad . \quad . \quad . \quad . \quad . \quad . \quad (4).$$

Also, since γ_c was adjusted to estimated equality with γ_m, we should have

$$\omega_1\omega_2 = pr_2M \quad . \quad . \quad . \quad . \quad . \quad . \quad (5),$$

where $\omega_1\omega_2$ was $1{\cdot}9\times10^{25}$
r_2 " 7×10^{15}
p " $7{\cdot}9\times10^3$,

and M calculated for two circuits forming a rectangle of 12,000 × 3,000 cms. is nearly $2{\cdot}0\times10^5$

$$\therefore\ pr_2M = 1{\cdot}1\times10^{25}.$$

The two members of equation (5) were thus experimentally of the same order, although the agreement is by no means close.

It may be fairly concluded that when two insulated wires run parallel and close together, a periodic E.M.F. acting on the circuit of one is liable to induce disturbances in the other, of which the greater part will be due to electrostatic effect unless the product $\omega_1\omega_2$ is less than the ratio of their electromagnetic to their electrostatic mutual capacity.

For parallel copper wires suspended at the same height above ground, this ratio is in Absolute El. Mag. measure.

$$\frac{M}{K} = 3{\cdot}6\left\{\left(\log_\epsilon\frac{2h}{r}\right)^2 - \left(\log_\epsilon\sqrt{1+\frac{4h^2}{d^2}}\right)^2\right\}\times10^{21} \quad (6),$$

where r is the radius of each of the wires (in centimetres).
" d is the distance between their axes "
" h is their common elevation above ground "

This ratio increases with the intervening distance d, so that the closer the wires the greater the electrostatic effect. The maximum value the ratio can attain under practical conditions is about 5×10^{23}, so that the product of the impedance in ohms of the primary and secondary circuits should not exceed 500,000 if magnetic induction is to be in the ascendant. Thus, if the primary circuit has 1000 ohms impedance the secondary should not have more than 500 ohms.

The particular pair of circuits experimented with in this case favoured electrostatic action more than would be usually the practice of overhead circuits, for the ratio M/k was only $2{\cdot}67\times10^{21}$, making the limiting ohmic product of the two circuits 2,670, while M/k is commonly about 2×10^{23} for a pair of pole lines, increasing the range of the ohmic product to 200,000. It is also to be observed that when the impedance in the primary circuit is small, and especially when it is situated at the transmitting end of the line, the variation of electrostatic potential, and, consequently, induction, will be greatly reduced, and the above rules for estimating the proportion of static and magnetic disturbance only approximate the truth when the impedance of the primary circuit is large, and particularly when situated at the receiving end of the line. As the lengths of the circuits increase, the greater will be the electrostatic share of disturbance, all other conditions remaining constant.

It is remarkable how small a mutual electrostatic capacity suffices to establish audible telephonic inductive disturbance of static nature, between two conductors. In fact, when the resistance to ground of the secondary circuit happens to be very high, the disturbance due to a small mutual static capacity would be hardly and often inappreciably increased if the two circuits were collected metallically.

For

$$\gamma_c = \frac{K\frac{de}{dt}}{\sqrt{1+p^2K^2r_2^2}} \quad . \quad . \quad . \quad (7),$$

and when r is more than ten times $\frac{1}{pK}$ this becomes very nearly

$$\gamma_c = \frac{pKE\cos pt}{pKr_2} = \frac{E\sin\left(pt+\frac{\pi}{2}\right)}{r_2} \quad . \quad . \quad (8),$$

and this is the strength of current that would be set up in the secondary circuit if the E.M.F. acted upon it directly.

As an instance of this, it was found that if the dynamo above mentioned were connected directly with the telephone through a condenser of 0·001 microfarad, and a resistance of 2·5 megohms in simple series, the clearly audible dynamo note was not appreciably strengthened by short circuiting the condenser. In fact, substituting these values in the last equation with $7{\cdot}9\times10^3$ for p, the ratio of the current without condenser to that with condenser in circuit is 1·0015 on the assumption of a pure sine variation of E.M.F. The same result should have followed with a condenser of only 0·00016 microfarad, allowing a ratio of 1·05 between the two currents as the limit of audible appreciation. This experiment can be verified with any dynamo and a few feet of gutta percha covered wire lying on the ground as a condenser and a graphit resistance in circuit with the telephone, after precautions are taken to ensure the necessary degree of insulation in the wire and instruments.

THE HELLESEN DRY CELL.

BY SHELFORD BIDWELL, F.R.S.

The following results of some practical tests of the new Hellesen dry cell, which I made for my own information, may probably be of general interest.

The experiments were made with 12 cells of the No. 2 type, measuring 3 × 3 × 6½in., as manufactured by Messrs. Siemens, Brothers and Co. The most striking characteristics of these cells, as distinguished from others of the same class, or, indeed, from any other primary battery that I know of, except those of the Bunsen and Grove type, are their small internal resistance and comparative freedom from polarisation. The cells were successively connected, each for a few seconds, with a galvanometer, the resistance of which, together with that of the leads, was about 0·005 ohm. The greatest current indicated was 12·9 ampere, the smallest 11·9, the mean for the 12 cells being 12·35. The E.M.F. at 17°C., in comparison with that of a standard Clark's cell, the E.M.F. of which at that temperature was taken to be 1·438 volt, ranged from 1·41 to 1·50 volt, the mean being 1·47 volt. Hence it appears that the mean internal resistance of a cell, when circuited through 0·005 ohm, is (assuming the E.M.F. to be unchanged) as low as 0·114 ohm. To find the resistance when little or no current was passing, the copper terminals of two cells were joined together, and the resistance of the opposed pair determined by the telephone bridge method. This was found to be about 0·196 ohm, or 0·098 ohm for each cell.

Six cells were circuited with an 8-volt 2½ c.p. lamp, which they brought to full incandescence. The current at starting was 1·02 ampere, falling in the course of two minutes to 0·95 ampere, a fall of about 7 per cent. The circuit was then broken, and when again closed, about 5½ hours afterwards, the current indicated was 1·01 ampere. For comparison, the same lamp was joined up with a battery of six bichromate cells, each of one gallon capacity, the zincs being immersed just so far as to give at starting a current of as nearly as possible 1·02 ampere. In two minutes the current had fallen to 0·8 ampere, a decrease of more than 20 per cent., nearly the whole of which occurred during the first minute.

One of the Hellesen cells, which had been previously used for several experiments, was connected with the galvanometer (resistance 0·005 ohm, including wires), and gave at first 12·2 amperes. In four minutes the current was 8·1 amperes, and in 11 minutes it had fallen to just half its original value, being only 6·1 amperes, when the cell was disconnected. The total output during the 11 minutes was calculated to be 1·4 ampere-hours, or 84 "ampere-minutes." After 45 minutes' rest the cell was found capable of giving 8 amperes, and two days later it gave 9·5 amperes, its E.M.F. having fallen from its original value of 1·41 to 1·35 volt, and its resistance on short circuit increased to nearly 0·14 ohm. Two days' further rest enabled the cell to generate 10·2 amperes; the E.M.F. appeared to have remained steady at 1·35 volt; the resistance must therefore have fallen to about 0·13 ohm. Of course no dry cell could be expected to bear such severe treatment with absolute impunity, and the small extent to which it suffered must be regarded as very satisfactory.

A single cell was competent to heat half an inch of No. 36 iron wire to bright redness; two cells instantly fused the wire. With one cell a small induction coil, having a secondary of 1,400 ohms, gave a half-inch spark, and with two cells a three-quarter inch spark, the longest for which the coil is intended. Other trials of a like nature need not be particularised.

To those who, like myself, are in the habit of working with electricity, and have not ready access to a dynamo and set of accumulators, these cells are likely to be of great value. One often requires for a brief period a current of greater constancy and strength than can be generated by bichromate or Leclanché cells, and I have many times had to go through the tedious and disagreeable operation of setting up and discharging a battery of Groves for the sake of obtaining current the total duration of which has not exceeded one or two minutes, or sometimes even a few seconds. In cases where a current of moderate strength, up to one or two amperes, and of fair constancy, is needed for a short time, the Hellesen battery seems capable of supplying all that is desired at a moment's notice and without any trouble. Outside the laboratory it can be employed for lighting small incandescent lamps, such as are used for surgical and microscopic purposes, or for seeing the time by a watch at night. It will work small motors and induction coils, and many other useful applications of it will suggest themselves. The advantages afforded by its cleanliness and portability need not be dwelt upon.

As to the life of the cells I cannot yet speak from experience. Other experimenters have stated it to be of long duration.*

ANDREWS' SYSTEM OF CONCENTRIC WIRING.

After an experience extending over several years, during which many experiments and different methods have been tried, Mr. J. D. F. Andrews has now brought his system of concentric wiring to a very satisfactory state of development. While having some points in common with the interior conduit system, which is so much spoken of in America, concentric cables for general wiring have rarely been used in this country, although a somewhat similar arrangement has been adopted for ship lighting.

One of the advantages claimed is safety against fire risks, since it is impossible to get at the inner conductor accidentally. Any leak must speedily result in a short circuit, and cannot give rise to charring of wood casing, &c.; but the essence of the system is that the external conductor affords a good mechanical protection to the inner one, and, except in very damp situations, no external insulation being used, the outer conductor is therefore practically earthed.

For this reason, and on account of the fact that the jointing of concentric cables is an operation which requires special care, the use of Mr. Andrews' system has been very considerably impeded, for engineers are, on the one hand, disinclined to employ a system to which their workmen must be specially educated, and, on the other hand, supply companies are too ready to throw the onus of maintaining a proper insulation upon their customers. At present, any one consumer's circuit is liable to be put to earth through the carelessness of another consumer or of the supply company itself, and for this reason there may be some hesitation in adopting a system in which the insulation of one pole is entirely dispensed with.

The Andrews system, however, possesses very important advantages, and has been thoroughly worked out, having been carried out in a most systematic manner, even to the design of special cut-outs and switches, where the advantages of the concentric principle are not so obvious. For the wiring of ships, dye-houses, mines, and under other difficult conditions, the system is particularly suitable. It has hitherto been employed chiefly by Mr. Andrews' firm, but we learn that several other firms have begun to adopt it. Owing to pressure on our space, we can only mention the following essential points in the construction of the cables and their uses.

They consist of a copper central conductor with vulcanised india rubber insulation, and armoured with galvanised iron wires, the latter forming the outer conductor. The cross sectional area of this armouring is usually made seven times that of the central conductor to maintain the same resistance in both. When the cables are larger, the armouring, or outer conductor, has to be laid on in two layers, in order to secure sufficient sectional area without increasing the diameter of the whole excessively.

The smaller sizes may, if required, be reduced in diameter to ¼ inch by using a copper outer conductor as well as an inner. When the wires are laid in plaster in the walls, the outer conductor is covered with a bituminous compound and yarn, for protection against any possible acids; beyond this no protection is used or required. An idea of the wiring may be gathered from the fact that the diameter of a wire to carry five lights is $\frac{5}{16}$ in., which takes the place of a wood casing measuring 1½in. × ½in., and larger cables are even smaller in proportion.

* See a report of some exhaustive tests which were made in the Physical Laboratory of Munich University, *The Electrician*, Vol. XXVI. p. 419.

Digitized by Google

The jointing of two lengths of wire together, or of a branch wire to a main, was a matter of considerable difficulty with concentric wiring before the introduction of Mr. Andrews' method. After preparing the place for a joint by cutting away the outer conductor and tapering the insulation from both sides, so as to expose the central conductor, the inner conductor of the branch, being previously prepared in the same way, is joined on and soldered. The insulation is then lapped on, first, a layer of pure rubber; second, an intermediate layer or separation of india rubber and soapstone; third, a lapping of india rubber mixed with sulphur. The joint thus prepared is lapped over with selecia cloth, and copper sheaths are placed over the spaces cut in the outer conductor. An iron mould is then held round the joint by screws, and molten metal fusible at a low temperature is poured in at a suitable gate; the mould when cold is removed, and the joint is complete. This method of making a good outer conductor by means of a copper sheath is most effectual, the parts of the joint are completely soldered together, and the heat thoroughly vulcanises the india rubber of the joint. Joints such as these are not only better than the old cast-iron or brass boxes, but are much cheaper, and as easily made.

SUB-STATION REGULATING APPARATUS.

A transformer sub-station regulating apparatus, the invention of Mr. Thomas Tomlinson, chief engineer of Messrs. Gordon and Co., is represented in Fig. 1. The requirements of a practical apparatus for the automatic control of transformer sub-stations are as follows:—First, it must use mechanical and not mercury contacts; second, it must be able to make and break circuits carrying the heaviest currents without any sparking whatever; third, if any one of the switches accidentally becomes heated it must at once be short circuited and thrown out of action; fourth, if any accident or breakdown whatever occurs to the apparatus, every transformer must at once be put into circuit. This condition is absolutely essential, and is the most important feature of the new apparatus.

If an apparatus such as we are describing fails while taking transformers out of circuit no harm is done beyond a waste of coal, but if a failure were to occur when putting them into circuit it would probably cause a fire and the destruction of the sub-station. This apparatus is intended to entirely guard against this source of failure.

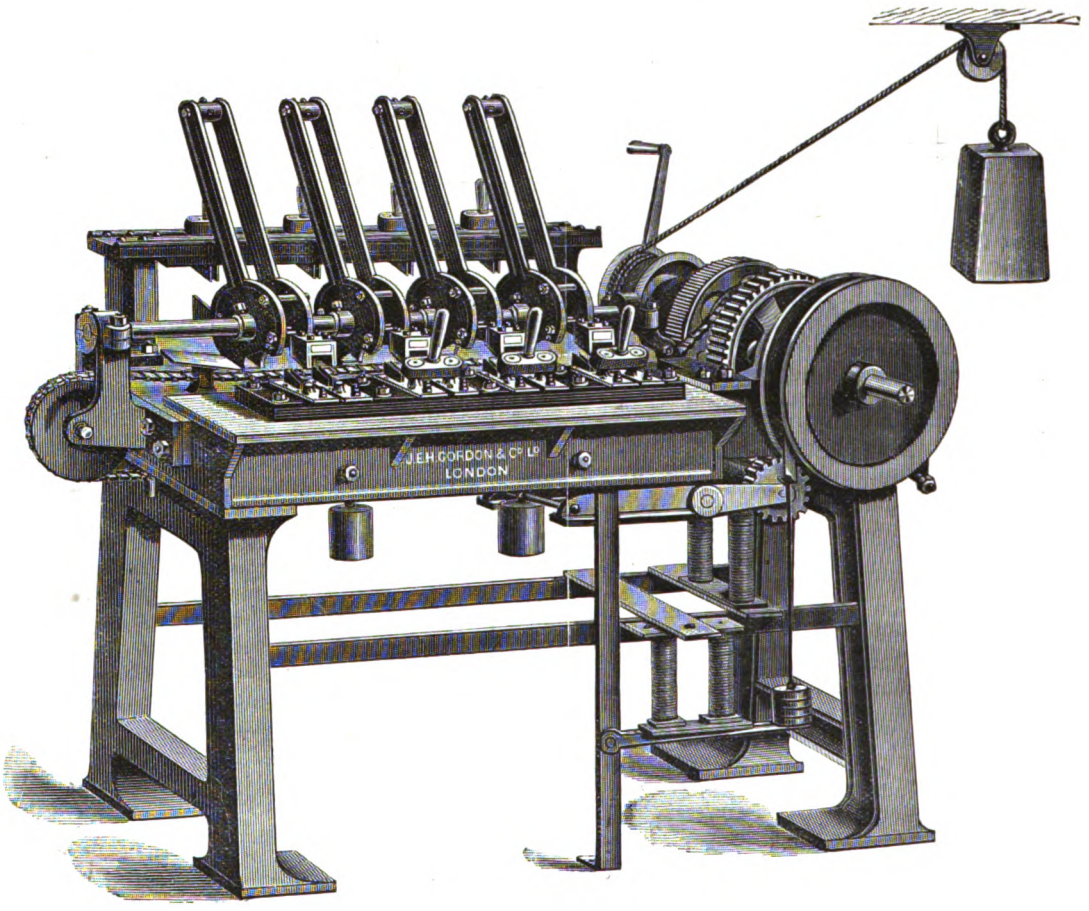

Fig. 1.

Four sets of switches are provided, and the transformers are arranged in five groups. One group is permanently connected to the mains and one more is connected through each set of switches respectively. The transformers are grouped as shown in Fig. 2. Suppose that one transformer is permanently connected to the mains, then one would be connected to the first switch, two to the second, four to the third, and eight to the fourth, so that the putting in of each switch doubles the number of transformers in circuit.

The switches are arranged to break the primary and secondary circuits simultaneously. The extra currents produced being in opposite directions, all sparking is prevented. With a load of 1,500 lamps on a single switch no spark whatever is visible. The switches are thrown over by a sliding carriage in the form of a double wedge, which runs backwards and forwards along the bed-plate of the machine, and, as it passes each switch, throws over a tumbling lever which strikes the switch suddenly in or out of contact. This carriage is moved by an endless chain actuated by two weights which are released respectively by two electro-magnets. The large weight which

Digitized by Google

takes transformers out of circuit has to be wound up once a week, and, as it takes out the transformers, it at the same time winds up a smaller weight ready to put them in again. If any failure whatever of the large driving weight occurs, or if the attendant forgets to wind it up, the small weight is always ready to put the whole of the transformers into circuit, and must do this before the apparatus becomes inoperative.

The wheels seen in the illustration are in gear with each other, through the pinions, and the whole system is kept at rest by the brake seen at the far side of the machine. When a current is sent through the lower magnet this brake is released and the large weight falls, turns the spindle, and through the cogwheels draws the carrier back and takes switches out. At the same time it winds up the small weight,

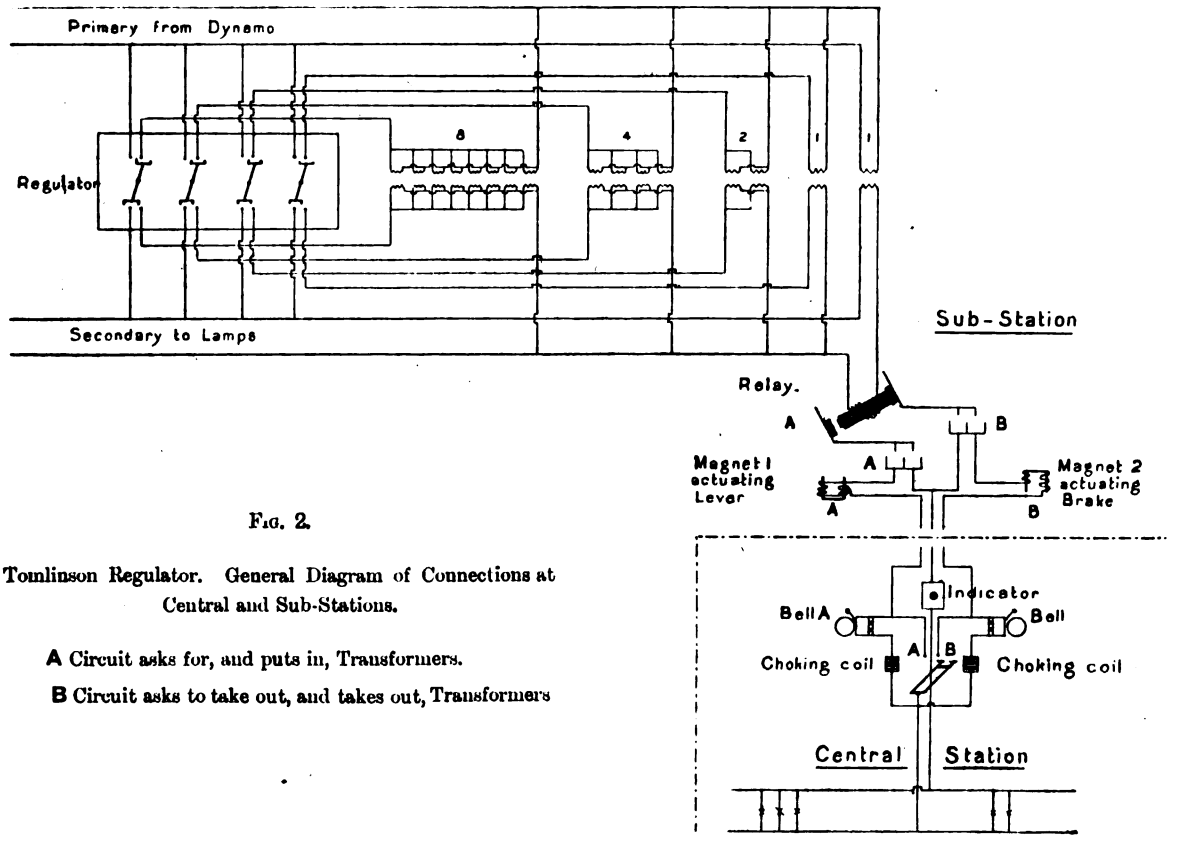

Fig. 2.

Tomlinson Regulator. General Diagram of Connections at Central and Sub-Stations.

A Circuit asks for, and puts in, Transformers.

B Circuit asks to take out, and takes out, Transformers

leaving it ready for putting the switches in again at any time. In case any switch should get hot, it would be short-circuited by the cross-pieces seen in Fig. 1 and shown in section in Fig. 3. These consist of hollow brass boxes mounted on an insulating frame, each box being electrically connected to a rod projecting inside the other box. Each box is lined with paraffin wax and filled with mercury. In case of heating, the paraffin melts and floats to the top of the mercury, which establishes a contact, and puts the switches out of action and puts transformers into circuit.

The method of actuating the apparatus is seen in Fig. 2. A double relay is provided, placed in the secondary circuit of the fixed tranformers. As soon as the current exceeds full load a contact is made, and a small current is sent through one of the magnets of the apparatus along a wire to the central station, where it passes through a choking coil and a bell. On the bell ringing, the attendant knows that more transformers must be put in, and he puts down a switch, which short circuits the choking coil and bell, and allows a sufficient current to pass to actuate the magnet and put a sufficient number of switches in. If the attendant should inadvertently hold down his contact-key too long the mistake will be corrected by the apparatus, as the circuit will break at the relay, and the machinery will cease to act. The magnet for taking out transformers is actuated in a precisely similar manner by the other part of the relay which acts when the current in the fixed transformers falls to less than half load.

In order to test this apparatus, a plant of 1,950 8 c.p. lights' capacity was, by the courtesy of the Brush Company, erected in their works, and connected to transformers kindly lent for the experiment by the Metropolitan Electric Supply Company. The plant was first run for 24 hours with the transformers connected in the ordinary manner, and then for 24 hours with them connected through the Tomlinson regulator, and coal and water were measured throughout the experiments. A preliminary experiment was made to find the coal used in running the engine, countershafting, and dynamo light, and this quantity was deducted. The electrical load was varied according to the ordinary requirements of the London stations (what is known as a 12·2 load factor being employed). The net result of the experiment was, that with the new apparatus 12¼ cwts. of coal were used in the 24 hours, and without it 16½ cwts., showing a saving of 26½ per cent. of the coal. From this Messrs. Gordon and Co. calculate that the saving amounts to 89lb. of coal, or in money to 10½d. per lamp per year. The average capital expenditure of a Supply Company is about £2. 5s. per 8 c.p. lamp, and this saving of 10½d. is, therefore, equal to 1¾ per cent. per annum on the capital which would be available to increase the dividends of the Supply Company. It must, however, be remembered that the conditions of the experiment, so far as the engine was concerned, were not those of actual central station working, where, if running at all, the engines are usually nearly fully loaded.

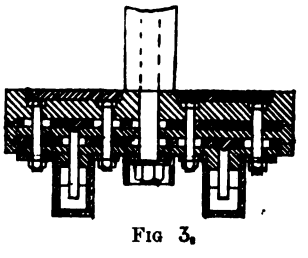

Fig 3.

Messrs. Gordon and Co. have published some rather intricate diagrams relating to the capital expenditure required for carrying out this system. They take a "lamp density" of one 8 c.p. lamp per yard run, which they say is an average pioneering density in London. Other curves represent densities of two

Digitized by Google

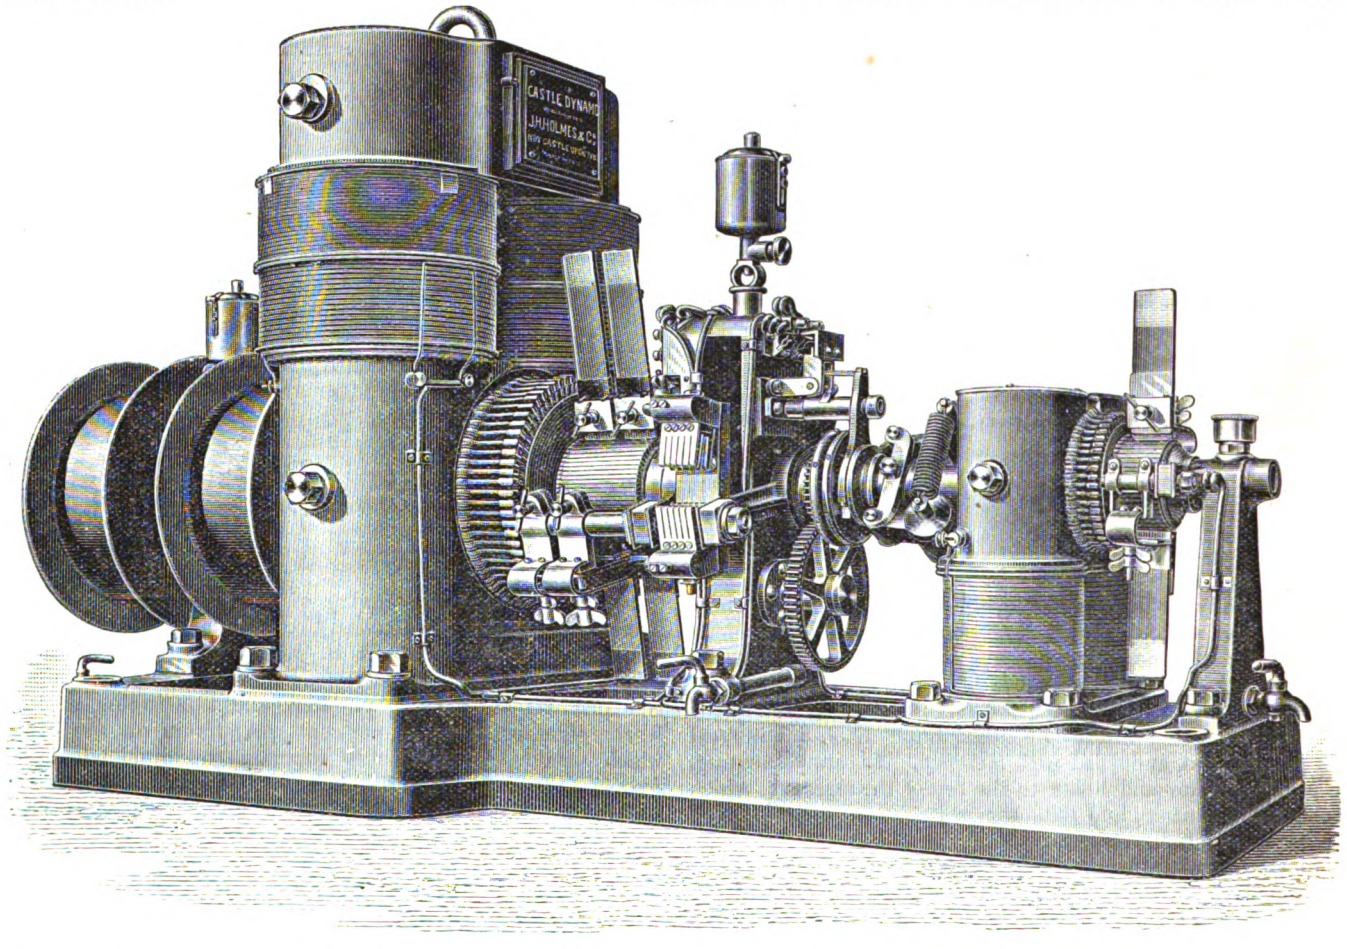
and four lamps per yard respectively. The figures show that with a pioneering density the capital cost, on the system under consideration, is about 5 per cent. dearer than that of the scattered transformer system, and that with all increased densities the capital cost is less.

They recommend that mains be laid with the sub-stations half a mile apart for pioneering, and that by afterwards inserting intermediate sub-stations so that they may be quarter of a mile apart, the same mains will serve when the density of supply is quadrupled.

The curves show that the position of the sub-station can be shifted for 200 yards without sensibly increasing capital cost, and thus some latitude is allowed in the selection of a site. These curves assume the lights to be approximately evenly distributed, but it should be noted that the existence of a large theatre or other public building at one point on the main would not affect the general calculations, as, if such a building were large enough to disturb the calculations, it would have a sub-station to itself.

J. H. HOLMES' RAILWAY TRAIN LIGHTING DYNAMO.

The accompanying illustration represents the improved Train Lighting Dynamos manufactured by Messrs. J. H. Holmes and Company, of Newcastle-on-Tyne, and 17, Coleman-street, London, E.C. This apparatus is being employed by the Midland Railway Company, more especially in connection with the electric lighting of their express trains. Mr. William Langdon, of Derby, explained its action very fully in his Paper read at the recent meeting of the Institute of Civil Engineers. It has also been supplied for French, German, and Russian railways.



The apparatus is the invention of Mr. J. H. Holmes, of Portland-road, Newcastle-on-Tyne, and is constructed with the object of maintaining a constant difference of potential at the terminals of the dynamo under a considerable variation of speed, and when driven in either direction. It depends upon the following principles, viz.:—Practically speaking, the volts of an ordinary separately excited dynamo vary directly as the speed at which the armature revolves; so, therefore, if the speed be increased, say from 500 revolutions per minute to 1,000 revolutions per minute, the electromotive force will be doubled. Also the electromotive force varies directly as the strength of the magnetic field, so that if the strength of field of a separately excited dynamo be reduced in the same proportion as the speed at which its armature revolves be increased, then the electromotive force of the armature will remain practically constant.

To this end two dynamos are arranged side by side, having their armatures upon the same shaft, so as to revolve together, main but with separate magnetic fields. The one is the generating machine, the other is for regulating the strength of the magnetic field of the generating armature. The magnets of the machines are separately excited from an external source, such as a set of accumulators, and the magnets of the generating armature are provided with two distinct exciting circuits. One circuit is an ordinary high resistance shunt circuit, and the other is of less resistance, and is coupled up to the source of current, so as to have the small regulating armature in series with it. The regulating armature is so coupled up that its electromotive force opposes the electromotive force of the external source of supply.

The high resistance shunt circuit is so proportioned that, at the highest speed at which it is intended to run the generating armature, it, without the aid of the regulating circuit, will give a magnetic field suitable for the required volts in the generating armature. When thus driven, the second exciting circuit ought to have no current passing

Digitized by Google

through it, a result which is brought about by the volts of the regulating armature being, at its highest speed, equal and opposite to the external pressure. If, however, the speed falls the volts of the regulating armature are lessened in the same proportion, and, being no longer equal to the external volts, a current will be permitted to flow through the second exciting circuit of the magnets of the generating armature, thus increasing the strength of the magnetic field to make up for reduction of speed, with the result of maintaining practically uniform volts in the generating armature.

When the speed falls to the lowest limit, say half the highest speed, the volts of the regulating armature will be half the volts of the external source of supply, so that it will be seen that it is necessary to calculate the proportions of the second exciting circuit of the generating armature magnets upon the basis of only half the electric pressure of the external source being available, and the resistance of the regulating armature forming part of the circuit resistance. At the lowest speed, therefore, half the exciting power upon the generating armature magnets will be produced by one coil having the full difference of potential of the external voltage at its terminals, and the other half by the second and lesser coil having half that difference of potential at its terminals, less, of course, by the drop of potential due to the resistance of the regulating armature which forms a portion of this circuit.

As arranged for use on a railway train, the armature is driven by belting from the axle of the guard's van, and a set of accumulators furnish the current for exciting the field-magnets. A centrifugal governor on the armature spindle automatically switches on the storage batteries for exciting the magnet coils of both the exciting and regulating machine as soon as the speed rises to the minimum speed at which the dynamo is intended to come into action, and it in like manner also switches off the current when the speed falls below the minimum speed. As the dynamo has to produce current when the train is running in either direction, the brushes which collect the current from the two armatures are made of wire gauze and are placed radially to the commutators, and the "lead" being automatically altered to meet the direction of rotation, the connections to the armatures are at the same time changed, so as to keep the polarity of the dynamo terminals always uniform. On the spindle carrying the armatures is also arranged a reversing switch which is actuated by friction discs which come into friction when the spindle slows down, but which run free on its attaining any degree of speed. The duty of this reversing switch is to insure correct polarity of current.

Working in conjunction with the dynamo is an automatic switch, such as is generally used in electric light installations having two coils, one, the highest resistance coil, connected to the dynamo terminals, and the other, the low resistance coil, in the main lighting circuit. The duty of this instrument is to switch on the dynamo when its pressure is sufficient to overcome the voltage of the accumulators and to charge them.

ON THE MEASUREMENT OF POWERFUL CURRENTS WITH A MIRROR-GALVANOMETER.*

BY A. OBERBECK.

By the principle adopted by the author, "the most powerful currents, without the addition of any shunt, give such small deflections that they can be measured with a mirror-galvanometer." A circuit of small radius surrounds a small magnet needle placed at or near the axis of the circle, and deflects the needle more strongly than a second circuit of which the radius is greater. The two circuits being placed concentrically in the same vertical plane, they can be shifted to such a distance from the needle that their influences on it are equal, and if the directions of flow are opposite the needle will remain in its normal position. By placing the circuits at a distance from the needle suitable to the strength of the current to be measured, the desired small deflection can be obtained.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

FRIDAY, May 15th.

FINSBURY TECHNICAL COLLEGE.

7.30 p.m. Students' Conversazione.

JUNIOR ENGINEERING SOCIETY.

8 p.m. Ordinary Meeting. Paper to be read and discussed: "Electrical Storage Batteries," by H. B. VORLEY, A.I.E.E.

ROYAL INSTITUTION.

9 p.m. Evening Discourse. "Crystalisation," by Prof. G. D. LIVEING, F.R.S.

SATURDAY, May 16th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture. "The Artificial Production of Cold," by H. GRAHAM-HARRIS, M. Inst. C.E.

WEDNESDAY, May 20th.

ROYAL METEOROLOGICAL SOCIETY.

7 p.m. Ordinary Meeting. Papers to be read: (1) "On the Vertical Circulation of the Atmosphere in relation to the Formation of Storms," by WILLIAM H. DINES, B.A. (2) "On Brocken Spectres in a London Fog," by A. W. CLAYDEN, M.A. (3) "An Account of the 'Leste,' or Hot Wind of Madeira," by H. COUPLAND TAYLOR, M.D. Mr. SHELFORD BIDWELL, F.R.S., will also exhibit an experiment showing the Effect of an Electrical Discharge upon the Condensation of Steam.

THURSDAY, May 21st.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting.

CHEMICAL SOCIETY.

8 p.m. Ordinary Meeting.

FRIDAY, May 22nd.

ROYAL INSTITUTION.

9 p.m. Evening Discourse. "The Molecular Process in Magnetic Induction." By Prof. J. A. EWING, F.R.S.

SATURDAY, May 23rd.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "The Artificial Production of Cold." By H. GRAHAM-HARRIS, M. Inst. C.E.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

Electrical Observations on the Hoher Sonnblick.—From the results of a series of experiments and of observations on the Hoher Sonnblick at a height of 10,168ft. above the sea-level, Profs. Elster and Geitel draw the following conclusions in the *Wiener Berichte*. (1.) The intensity of the most refrangible rays of the sun's spectrum, as measured by its discharging action on negatively electrified surfaces of amalgamated zinc, increases with the height above level ground, in such a manner that at a height of 10,168ft. it is *twice* as great as on ordinary level ground. (2.) Notwithstanding this increase, no new actinometrically active substances were discovered. (3.) Waterfalls can produce negative falls of potential in a valley, and even to considerable heights, 1,600ft. (4.) Before the outburst of storms observed on the 16th, 18th, and 20th July, 1890, the positive fall of potential, within the cloud which sent only a small quantity of rain, sank slowly down to the value zero, at which it then remained for a long time, perhaps two to three hours, until the electrical process in the cloud definitely came to an end. (5.) In storm-clouds the atmospheric electricity usually changes its sign after a discharge of lightning, as with storms in the plain. (6.) St. Elmo's fire was found to constantly accompany storms; it was not found that *negative* St. Elmo's fire was more infrequent than *positive*. (7.) The observation that negative St. Elmo's fire follows bluish lightning, and positive, reddish lightning, was frequently confirmed. The direction, then, of the electrical current which traverses the atmosphere in the form of lightning appears to have an influence on the colour of lightning.

(President of the Institution of Electrical Engineers), have been issued as Supplements to "THE ELECTRICIAN." *A few Copies of these admirably-executed Steel Engravings can be supplied, price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price, post free, 4s. 6d.*

THE UNIVERSITY OF LONDON AND ITS DEGREES.

The great interest which has been aroused in educational and medical circles in connection with the proposed reconstruction of the University of London only indirectly concerns most of our readers. It is evidently recognised by the authorities of this institution that it falls lamentably behind an ideal university, and a very vigorous attempt has been made to extend its usefulness. The older and larger universities have a constitution which cannot be easily defined in a few words. A large number of the younger members of the Universities of Oxford and Cambridge join, go through their course, and leave, without acquiring any clear idea as to what their universities really are. They are often looked upon by them as a collection of colleges united together under an organising governing body. Since both the colleges and the university provide lectures, and since both hold sundry examinations, it is not uncommon to find some doubt existing as to whether the college or the university grant degrees. The old idea of a university was "a school where all arts and faculties are taught." Mr. BOMPAS observed at the stormy meeting of convocation on Tuesday that "the University of London had discharged the function of granting a degree which was real evidence of knowledge," and he thus apparently summed up its whole purpose,

Digitized by Google

The main object of the proposed new Charter was to raise the University of London from its somewhat insignificant position by making it a teaching University. To do this, something more than an examination hall is required, but there has been no suggestion of new lecture rooms and laboratories. Lord Justice FRY, writing to *The Times*, pleaded that the scheme would bring together the great educational institutions of the metropolis; it would give to University College and to King's College a place on the councils of the University, and would "take account of their educational work in the granting of the Arts degrees. It would also offer a place to the provincial colleges." Why the admirable institutions founded by the City and Guilds of London have not been alluded to in the discussions; where the line was to be drawn in defining the proposed agglomerate of schools; whether Morley College and the excellent Birkbeck Institute and the Regent Street Polytechnic were to be embraced, we have not yet heard; but it does not matter much, as the decision of the Convocation was negative, and, as Lord Justice FRY intimated, the matter is at an end, and the reluctance of the two first-named colleges to participate in the scheme need not be dwelt upon.

The University of London is to be considered, then, as a mere degree-granting body, and the question arises, What is the value of its degrees to education generally, and to the individual recipients? The speaker whom we have already quoted thinks that the University of London has done much to raise the standards of the older universities, and alluded to the worth of the London M.A. degree. The peculiarity of the London degrees is, that the higher ones are of considerably more importance than the corresponding degree at Oxford or Cambridge; while to the lower ones is to be attributed nearly all the mischievous cramming, crammers, and cram-books that have so degraded modern science. It is a well known and an obvious defect in the degrees of Oxford and Cambridge that a B.A. is given alike to one who has just scraped through a pass examination and to the most brilliant of the first class in the honour list; and, after the lapse of three years and the payment of a fee, the M.A. is conferred on each. The latter degree is always proceeded to by those who devote themselves to clerical or educational work, but is not unfrequently neglected by those who are engaged in other professions. There is nothing which corresponds with the London M.A. or the D.Sc. The latter means something more than first-class honours in the Natural Science Tripos of Cambridge, and is a very noteworthy distinction. To the B.Sc., on the other hand, we have a very great aversion, and we are continually reminded of it by the steady stream of text-books which are written to "meet its requirements." The object of the University of London is to examine those who have studied the various subjects by private reading or otherwise. Anyone who has educated himself is invited to come to the testing machine, to drop his guineas in the slot, and to try his strength. The examinee may thus estimate the quantity and quality of the knowledge which he has acquired, and if he receives a degree he has something to show by way of evidence. But no sooner was this system in thorough working order, than a trade was created in the manufacture of students and of books for their use, and anyone of decent intelligence is invited to pay £2. 17s. 6d., or some such amount, in return for which he will be crammed for the matriculation, and, if he fail, the process will be repeated till he passes, or is sick of it. And this is called education. The B.Sc. is an admirable test for the private student whose reading might be most usefully guided by a well prepared syllabus, but this end has been well nigh lost sight of; it has a certain small but defined commercial value in the educational profession as a hall-mark, it affords a livelihood to a number of crammers who encourage the system without attempting to provide any real education, and who bring a permanent discredit on science by the production of the books to which we have alluded.

It is held by some persons that it was a pity that an agitation was raised at Cambridge for the admission of women to the existing examinations, the whole system being established on a wrong basis, and that if they had held aloof and had regarded higher education as a means of making new knowledge, instead of producing examination-passing students, the present system which culminates in examinations might have been revolutionized. There are a few cases in which wholesale scientific teaching is admissible, as, for example, the passing of medical students through an elementary course of physics. At Cambridge such work is done in a special building set apart, with a few demonstrators, for the purpose as it would interfere with the work done at the Cavendish Laboratory.

The University of London, if supplemented by a teaching department, will not make a University in the full sense of the word. No University extensions or *olla podrida* of colleges or "Lord HERSCHELL'S idea of an Imperial degree-granting University for the Empire, with its system of London and provincial colleges," will contribute to the advancement of science or to the benefit of individuals. A very intelligible argument against the establishment of a teaching department is that at present all comers are at an equal advantage, but if the teaching scheme were adopted, those who made use of it would be better able to meet the examiners than the private student or one who might come from some unattached institution. The work that is being done by the numerous Technical Colleges is as valuable as it is varied, both in subject matter and in general character. The desideratum of to-day in London, as far as scientific education is concerned, is the thorough equipment of existing institutions with first-rate laboratories. The £50,000 apiece for which King's College and University College appealed a few months ago would do more good than any new Charter. Scientific education needs expensive plant, and the students' fees cannot defray the current expenses. It is to be regretted that a number of students attend the lectures in physics and chemistry, for which but a small payment is asked, who cannot afford to attend the laboratories and engage in practical work.

The cramming establishments have to provide laboratories, and it is probable that the cast-iron limitations of their teaching has less harmful influence even in the department of chemistry called "test-tubing" than in the book work. First-rate laboratories for the students and for the professors can only be provided by endowment, and the same source must provide for the teaching staff. Charters will not attract good men; these have a definite market value, but the high education which they provide has none. Since London colleges must be self contained, the benefits of the proposed amalgamation are not at all clear. The system of inter-collegiate lectures, which answers admirably at the older universities, cannot be carried out in the metropolis. A student cannot take his mechanics from Prof. PERRY, his chemistry from Prof. ARMSTRONG, his physics from Prof. CAREY-FOSTER, and drop in for his mathematics from Prof. HUDSON. The examinations held at the existing institutions receive very careful attention, and are amply sufficient for satisfying the students as to the proficiency to which they have attained. The University of London would do well to continue, as heretofore, to play the part of the Sphinx, and to propound questions to all who may care to present themselves.

ELECTRIC AND MAGNETIC THEORIES.

BY SILVANUS P. THOMPSON, D.SC.

§ 1. The proposition to which I invite the attention of Mr. J. T. Sprague is as follows:—

In an electric circuit, the energy which is transferred from the source to the work is so transferred by the operation of the medium surrounding the circuit, the energy passing laterally out of the circuit at the place called the source into the surrounding medium, and passing back laterally into the circuit at the place where the work is done; and the said energy is not conveyed longitudinally along the substance of the copper (or other) wire or conductor, from the source to the work, by an end thrust, as in the case of the transmission of power hydraulically along a pipe full of water.

I trust that all doubt as to the terms of this proposition are already settled by the preliminary propositions of p. 464, as agreed to be amended, on p. 495.

§ 2. The line along which I propose to advance is as follows:—I propose to show, firstly, that there are certain cases in which beyond contest the energy is transferred from the source to the work across the medium. I shall show this first in some cases where there is no metallic or other conductor which can possibly effect a longitudinal transfer, and in which, therefore, the transfer is lateral. I shall then show this in a case or cases in which, though there is present a metallic conductor along which a longitudinal transfer by conduction might occur if that method of transfer of energy were possible, part, at least, of the energy is transferred laterally by the medium. After the discussion of some further cases, and reserving some others for a future occasion, I shall then put to Mr. Sprague the query whether he has evidence of any case in which there is transference of energy that cannot be accounted for by the hypothesis of a lateral transfer through the medium. In short, my argument will be this: since, in those cases in which the hypothesis of lateral transfer cannot in the present state of science be directly demonstrated, there is no evidence to show that the transfer takes place in any other way; then, in the absence of such evidence, one is logically driven to the conclusion that in all cases the mode of transfer is the same as in those cases in which a direct demonstration is possible.

I state this line of argument at the outset, because I wish it to be understood from the beginning what use is intended to be made of the cases that first put forward; for it may be frankly admitted that down to the present moment there are some cases for which I think no direct mode of proof has yet been devised.

§ 3. Incidentally, I now make a remark that is, I believe, of utmost importance to everyone who wishes to enter into the real marrow of this question. We have lived all our lives in a dielectric—the air. The fact that we have grown up in such a medium, and have made our electrical experiments in it, and have acquired our electrical knowledge while living in it, cannot but have an immense effect in moulding and limiting all our conceptions of electric action. Had the atmosphere around us been a good conductor—such as quicksilver, for example—our knowledge of electricity would have been gained in quite a different order of discoveries. Our fundamental ideas, and the language with which we clothed them, would have been quite different from what they are. Living in a dielectric medium, the problem of transmitting energy electrically from one place, A, to another place, B, necessitated that we should construct a metallic conductor from A to B, and our thoughts became concentrated on the *conductor*, which, in our ignorance, we conceived as carrying an invisible current of a supposed fluid, though no mortal man has yet been able to say in which direction the alleged current flowed. Had we, however, lived immersed in a conductive medium, such as quicksilver, the problem presented to us would have taken an entirely different aspect. We should have found metallic wires to be not of the slightest help; eventually it would have been found that a tubular septum of some such dielectric material as gutta-percha would serve the purpose of enabling energy to be transferred from one place to another. We should have laid a tube of gutta-percha through the conducting ocean of quicksilver, like an Atlantic cable. It probably would never occur to us, or only dimly, that anything was carried by the quicksilver either inside or outside the tube; we should have regarded the dielectric tube as the precious all-important instrument of communication, and should have considered it as the carrier of the impulses, by whatever name we called them.

It is to this unfamiliar standpoint that we have now, with pains and trouble occasioned by our necessarily one-sided training, to bring ourselves round. When we contemplate the modern theory as to the propagation of electric actions we have to try to cut ourselves adrift from the point of view of persons who happen to have been born and to have lived and moved immersed in a dielectric, and whose whole thought is tinged with ideas bred of that circumstance. Many of the difficulties which arise to the electrical student in considering the modern theories, some, indeed, of those raised by Mr. Sprague in his articles, are simply the natural inevitable result of this environment of thought.

§ 4. I proceed at once to those cases in which it can be directly demonstrated that the energy which impels the current travels across the dielectric medium. Fig. 1 represents two circuits in which there have been inserted two coils, A and B, having such relative positions as to possess mutual induction. In the circuit of A is inserted a suitable battery or other source, S, of current, and a key, K. In the circuit of B is inserted a galvanometer, G. When K is depressed a current is established in A. Were B absent, or not closed on itself, the current in A will take a certain time to rise to its full strength. When B is present, the variable period of the current in A is of shorter duration,

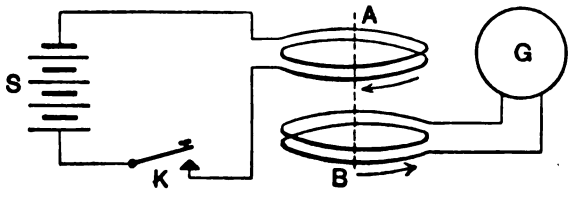

FIG. 1

more energy being drawn from the battery S. But during this period, while the current in A has been rising in strength, an induced current will be observed to circulate in B; and will manifest itself by moving the needle of the galvanometer, and by slightly heating the wire of the B circuit. This means that some work has been done in B; at the expense of the actions in S which furnished the energy to the system. How, then, did the energy pass from S to the B circuit? Evidently, by the intermediate agency of the coil A, from which the energy has crossed the space separating it from the B circuit. This energy has been transmitted by the medium which lies between, and has obviously entered the coils of the B circuit in directions which are transverse to the flow of the induction current. It was proved many years ago by Sir William Thomson that, in such an operation as this, the energy drawn from the source is just double that which is manifested as heat in the B circuit. Of the whole energy thus drawn from the source (over and above that which is accounted for in the A circuit) one-half only is manifested in the transient current in the B circuit; the other half is employed in bringing the medium between A and B into the peculiar state of stress which subsists and increases the potential energy of the system while it lasts. On breaking circuit at K this energy also disappears from the medium; and a second induction current in the B circuit (this time in the opposite direction to the former induction current) announces that this other half of the energy has now been transferred into the circuit B and spent therein. In all these there is nothing which would in the remotest manner suggest an end thrust in the B circuit. The energy has entered laterally from the medium into the conductor, and done its work.

That the medium is *the* agent in this operation there can be no manner of doubt; for the amount of the action is found to depend in the most direct and striking way upon the medium

Digitized by Google

itself. Let the conductive circuit, A and B, be unchanged in every respect, but let a bundle of iron wires be inserted as a core, in place of air, where the dotted line lies from A to B. At once there is an enormous augmentation of the actions. Ten, twenty, or even fifty times as much energy as before is now transferred at each opening and closing of the key from the circuit A to the circuit B. It is obvious that the energy path is through the medium, and is affected by the choice of materials to be used as a medium.

§ 5. Now let us consider a second case. Let A (Fig. 2) be a Hertz oscillator, consisting of two metal rods terminated by polished balls, and ending in flat metal sheets. They are connected to the discharging apparatus of an inductorium which causes occasional sparks to pass across between the balls. Every spark (as can be demonstrated in various ways) consists of a series of rapid discharges oscillating across the gap between the balls.

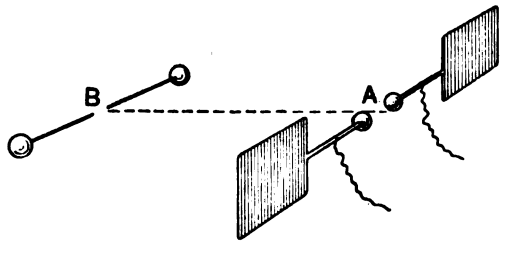

FIG. 2.

Opposite the spark gap of A is placed a Hertz explorer, B, consisting of two metal rods of suitable length, with a minute gap between them. As every spark flashes across at A, a corresponding spark is seen at B, provided the exploring device is properly adjusted and held parallel to the rods of the oscillator. It is obvious that in this case some of the energy imparted to the oscillator, A, has crossed the intervening medium to B, and here manifests itself in light and heat. The transfer is again lateral, by means of the medium, not longitudinal, or by an end thrust along a wire.

§ 6. Let us consider a third case, namely, one of Prof. Elihu Thomson's experiments with alternating currents. Let an alternating current be introduced into a coil, A, surrounding a bundle of iron wires as a core. Opposite it let a sheet of copper, B, be placed, as in Fig. 3. If B is held still it is found

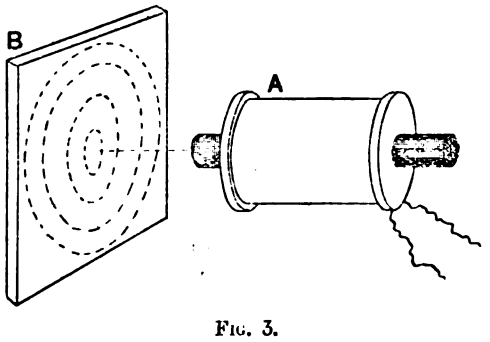

FIG. 3.

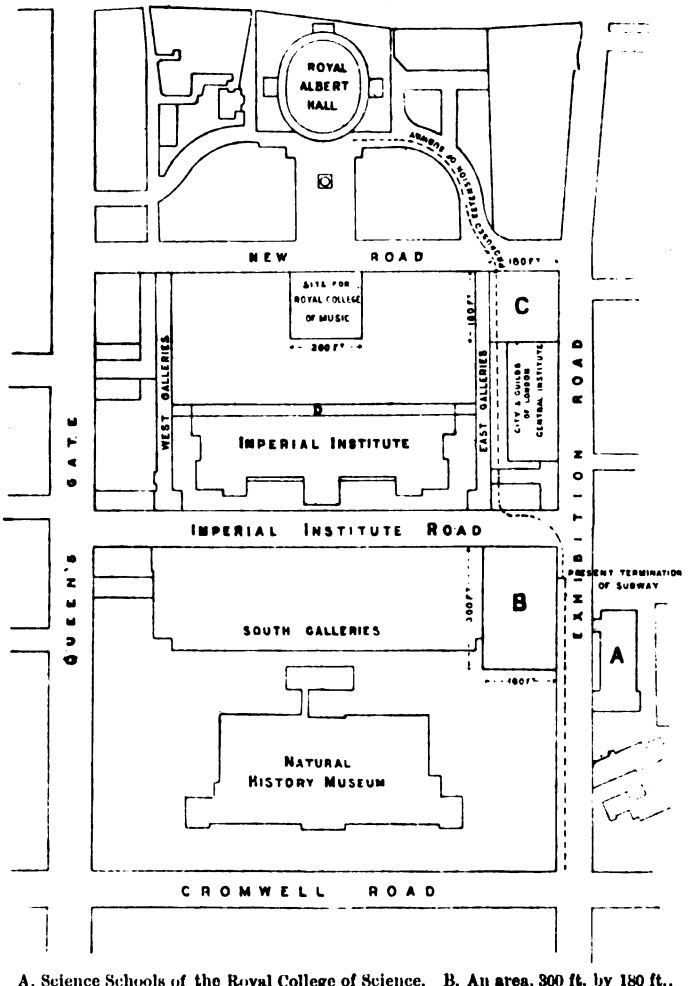
to heat; and by proper contrivances it is easy to show that alternating currents are being set up in it, in eddies which centre, approximately, around the axial line between A and B. These currents may be of great strength, as evidenced by the rapid and considerable heating, and by the powerful mechanical repulsion which ensues between B and A. Again, this is a case in which it is clear that the energy which has traversed the apparatus from A to B has crossed the medium separating the two, and has entered the copper sheet by paths the general direction of which is at right angles to the same, and therefore laterally with respect to the induced currents. There is nothing to suggest an end-thrust as propelling the currents in question.

(To be continued.)

SCIENCE versus ART AT SOUTH KENSINGTON.

The accompanying plan will explain to our readers the details of the very important discussion which has arisen as to the disposal by the Government of land for a new picture gallery. The area B has been selected by Mr. Tate as the site for the Gallery of British Art which he so liberally offers to build. Its dimensions are said to be much too large for an expenditure of £80,000, which sum it has been decided shall not be increased by the addition of public money.



A, Science Schools of the Royal College of Science. B, An area, 300 ft. by 180 ft., at present occupied by a Physical Laboratory and two small Observatories of Mr. Lockyer. C, a site, 150 ft. by 180 ft., partly occupied by the School of Art Needlework. D, Corridors now in course of erection.

The area C would have immediate connection with the east galleries, and these are pronounced by the leading artists to be the best lighted and best proportioned in England. The Science collection is at present scattered all over the place, as far as the west galleries.

NOTE ON A MODIFICATION OF THE METHOD OF CONNECTING UP TELEPHONIC APPARATUS.*

BY E. MASSIN.

The London-Paris telephone line was completed on Saturday, March 14th, by the laying of the submarine cable from Sangatte to St. Margaret's Bay. The following Tuesday the first experiment showed that success had crowned the enterprise, and that communication could be easily effected between the central offices. All the instruments adopted in France for subterranean lines enabled conversation to be carried on more or less favourably. With the Gower-Bell, the Post Office instrument, communications were also exchanged without difficulty. Amongst the apparatus tried, the one which seemed to me to be the best, from the point of view of volume and clearness of sound, was the Roulez instrument.

In the Roulez instrument, the vibrating diaphragm is a carbon plate 10cms. in diameter. On this diaphragm is screwed a block of carbon 7cms. long, its face of contact being covered with a sheet of

* *Annales Télégraphiques*, Vol. XVIII. Third Series.

Digitized by Google

Bristol-board (Fig. 1), which acts as an insulator. The plate and block, insulated from one another by the Bristol-board, constitute the two poles of the microphone. The current gets from one pole to the other across fragments of incandescent lamp filaments arranged in three holes hollowed out of the carbon block and insulating sheet.

I have stated that conversation was easy between the General Post Office and the Paris central office; but as soon as we added to the main line the high resistance gutta-percha covered cables which connect the central to the secondary offices, the state of affairs was altered, the voice was muffled, and while conversation was still practicable between two persons accustomed to converse by telephone, it was not, generally speaking, possible. If we took the most complex case, and tried to speak from a London subscriber's house to one at Paris, the voice was clear enough, but the volume of sound was insufficient for telephonic working.

With the existing urban lines only one apparatus was able to give the desired quality and volume of sound, namely, the Roulez microphone, arranged as in Fig. 2, where the receivers and the secondary of the induction coil are placed in parallel across the line. A special key closes the telephonic circuit, either of the receivers or of the secondary, but does not allow the two to be simultaneously to line. Instead of this arrangement, which was carried out in the apparatus employed at the Paris Observatory and the Treasury, one can keep both receivers and secondary in series and constantly in circuit, as is usually done, and content oneself by neutralising one or the other of the two parts by short circuiting them.

The theoretical advantages of the above modification of the usual arrangement are as follows: (1) The receivers do not spoil the transmission and the presence of the transmitter does not weaken the sound received; (2) the operator in the case of long lines does not have his ears deafened from the beginning by the currents

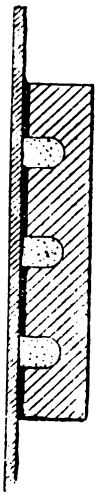


Fig. 1.

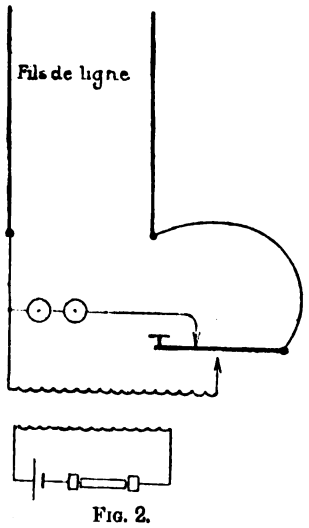

Fig. 2.

generated by his own transmitter and traversing his receivers; (3) it is possible to increase the currents in the primary without fear of having currents in the microphone at the far end to cause troublesome crackling in the receivers at that end.

In the experiments between the Paris Observatory and the Treasury, a battery of 10 Lalande cells arranged in series was used. With a *non-modified* Roulez this battery produced deafening cracklings in the receivers, and conversation was impossible. But with the modified instrument conversation was perfect, the voice arrived loud and clear, and one could even keep the receivers at some little distance from the ears and still perfectly understand what was being said.

This modification, therefore, possesses undeniable practical advantages. Applied to the Roulez instrument it increased the intensity of the sounds received at the Observatory and at the Treasury by 4 to 1, thus rendering conversation possible between a London branch office and a Paris subscriber, to the exclusion of all other instruments tested. But the arrangement possesses two drawbacks, which are—firstly, the manipulation of the key; and, secondly, the impossibility of interrupting one's correspondent, who cannot be made to hear so long as he is transmitting. The key is fitted in the handle of one of the receivers, and is manipulated with the thumb of the right hand; the button is pressed when transmitting, and freed when listening. This very simple manœuvre is easily learnt, and after two or three minutes' conversation the button is automatically moved without thinking. The impossibility of cutting into the conversation seems to me the only real disadvantage of the arrangement described, and we may ask whether this defect is not greatly compensated for by the increased range given to the telephone, and by the possibility of establishing communication between a Paris subscriber and a London branch office.

ON SOME EFFECTS OF ALTERNATING-CURRENT FLOW IN CIRCUITS HAVING CAPACITY AND SELF-INDUCTION.*

BY DR. J. A. FLEMING.

(Continued from page 202.)

9. These considerations point out that, in applying either transformers or alternators to circuits which have capacity, we must have regard to the fact that, for certain critical values of the inductance and the capacity for given frequencies, there may be a very considerable increase fn the potential difference of the two sides of the condenser over and above that of the poles of the alternator or transformer when no condenser is present. Such effects have been noticed in practice of late. It has been frequently found that if a transformer which gives on its open secondary circuit a certain potential difference is applied to test the insulation of a length of concentric cable by connecting its terminals to the two conductors, the far ends of the cable being insulated, under some circumstances an increased potential difference is observed between the free ends of the cable over and above that at the terminals of the transformer when the cable is not connected to it. When transformers have been employed to test the insulation of armatures of high-pressure alternators, it has been noticed that under some circumstances large snapping sparks will jump off over air distances which could not possibly permit discharges at the actual potential difference of the secondary terminals of the transformer so used when unconnected with any such body having capacity.

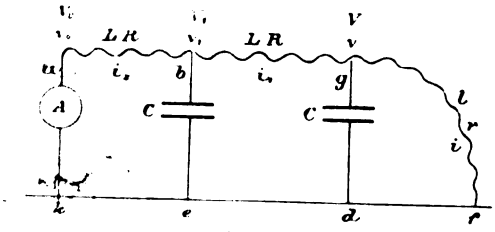

Fig. 7.

In employing an alternator or transformer to test insulation between two opposed conductors, or in any way in which the opposed terminals gain capacity, it is necessary to be on the watch for this possible rise of pressure, and not to infer, because a transformer gives, say, 2,000 volts on open circuit between its poles when measured with an electrostatic voltmeter, that therefore this is the measure of the pressure which is being applied to a dielectric which forms the insulator of a condenser joined in across the poles of that transformer.

I am not at all sure that, under some circumstances, errors may not be committed in the mere use of an electrostatic voltmeter to measure potential difference between the poles of an alternator or a transformer, if that voltmeter happens to possess a certain capacity in relation to the inductance of the circuit in which it is joined in parallel.

10. It is easy to treat in the foregoing manner another case slightly more complicated.

Let the inductive line $a\,b\,g\,f$ (Fig. 7) be divided into three sections, $a\,b$ and $b\,g$ having each resistance R and inductance L, and the section $g\,f$ having r and l for similar quantities. Let condensers of capacity C be inserted in b and g. If v and v_1 are the potentials at any instant of the condenser terminals, and i, i_1, and i_2 the instantaneous currents in the sections of the line, and I, I_1, and I_2 the maximum values of these periodic currents, it is not difficult to show, with our former notation, that

$$v_1 = \frac{I}{C\,p}\Big((B\,a+A\,b)\sin p\,t+(B\,b-A\,a+1)\cos p\,t\Big) \quad . \quad (21),$$

but

$$i_2 = i_1 + C\frac{d\,v_1}{d\,t},$$

and

$$i_1 = I\,(a\sin p\,t + b\cos p\,t) \quad . \quad . \quad . \quad . \quad . \quad (22)$$

by (12). Hence we have,

$$i_2 = I\{(A\,a-B\,b+a-1)\sin p\,t+(B\,a+A\,b+b)\cos p\,t\} \quad . \quad (23),$$

from which we deduce that the ratio of the maximum currents, I_2 and I_1, in the first and second sections of the line, is given by the equation,

$$I_2 = I\sqrt{(A+1^2+B^2)\,(a^2+b^2)+a\,b\,A-B-2\,a\,A+1+2\,B\,b+1} \quad (24),$$

and in like manner the ratio of the maximum values of the potentials V_0 and V_1 can be obtained.

* Paper read May 7, 1891, before the Institution of Electrical Engineers.

Digitized by Google

It is possible also to show that for certain critical values of L, C, and R, the potentials V_0, V_1, and V, at the terminals of the alternator and at those of the condensers, progressively increase, as well as the currents in the sections of the line. Cases of this kind, beyond a single condenser, are best treated as Mr. Blakesley has done—by geometrical methods.

11. In the limited case of a condenser charged by an alternating electromotive force through an inductive circuit, we may arrive at a direct analytical solution of the relation between the coefficients of induction and capacity of the system and the mean square of the charging current, and of the potential difference at the poles of the condenser or at those of the alternator, as follows:—As before, let V_0 and v_0 stand for the maximum and instantaneous values of the potential difference at the poles of the alternator; let V_1 and v_1 be the same quantities at the terminals of the condenser; and let I and i be the same for the current flowing into the condenser having a capacity C, whilst the line connecting the condenser with the alternator has an inductance L and a resistance R. We have, then, by fundamental equations, the following relations:—

$$L\frac{d\,i}{d\,t}+R\,i=v_0-v_1 \quad . \quad . \quad . \quad . \quad . \quad (25),$$

$$i=C\frac{d\,v_1}{d\,t} \quad . \quad . \quad . \quad . \quad . \quad . \quad (26).$$

Also, let $v_0=V_0 \sin p\,t$, and hence

$$i=I \sin (p\,t+\theta),$$

where θ is the angle of lag of current behind the impressed electromotive force.

Eliminating v_1 from the above equations we have,

$$L\frac{d^2\,i}{d\,t^2}+R\frac{d\,i}{d\,t}+\frac{i}{C}=p\,V_0 \cos.\ p\,t \quad . \quad . \quad . \quad (27),$$

or since, for simple periodic currents, $-p^2=\frac{d^2}{d\,t^2}$, we have,

$$\frac{d\,i}{d\,t}+\frac{1-C\,L\,p^2}{C\,R}\,i=\frac{p\,V_0}{R}\cos.\ p\,t \quad . \quad . \quad . \quad (28).$$

This equation is of the form,

$$\frac{d\,i}{d\,t}+Pi=Q\cos p\,t,$$

the solution of which is known to be

$$i=\frac{Q\,P}{P^2+p^2}\cos p\,t+\frac{Q\,p}{P^2+p^2}\sin p\,t;$$

and an easy transformation gives us, therefore, the solution for the particular case in hand as

$$i=\frac{(1-C\,L\,p^2)\cos p\,t+C\,R\,p\sin p\,t}{(1-C\,L\,p^2)^2+C^2\,R^2\,p^2}\,C\,p\,V_0 \quad . \quad . \quad (29).$$

This can be written also,

$$i=\frac{C\,p\,V_0}{\sqrt{1-C\,L\,p^2)^2+C^2\,R^2\,p^2}}\sin(p\,t-\phi) \quad . \quad . \quad (30),$$

and the maximum value of i, viz., I, is, therefore,

$$I=\frac{C\,p}{\sqrt{(1-C\,L\,p^2)^2+C^2\,R^2\,p^2}}\,V_0. \quad . \quad . \quad . \quad (31).$$

This gives us the mean square, or dynamometer, value of the current I flowing into the condenser in terms of the mean square value of the potential difference of the poles of the alternator and the coefficients C, L, R, and p. If $C\,L\,p^2=1$, then the value of I reduces to $\frac{V_0}{R}$; in other words, for this particular value of the relation between the inductance and the capacity, the whole system of inductive charging line and condenser acts as if it were a non-inductive conductor of resistance R.

We see also that this equation (31) can be made use of to determine L from observed values of I_1, V_0, C, R, and p, or else C when L is known. The value of the mean inductance of the line is given by the equation,

$$L=\left(\frac{1}{C\,p^2}-\frac{1}{p}\sqrt{\frac{V_0^2}{I^2}-R^2}\right) \quad . \quad . \quad . \quad . \quad (32),$$

which gives L in terms of observable quantities.

The current at any instant flowing across the dielectric of the cable may be spoken of as the *condenser current*. It is always in magnitude equal to the product of the capacity of the condenser and the time rate of change of the mean potential difference, v_1, of its surfaces. It follows that, in the case of simple periodic currents, the square root of the mean square of this current, I, which is what we measure with a dynamometer, is equal to the product of the square root of the mean square of the condenser plate potential difference V_1, and the quantity $C\,p$, where C is the capacity of the condenser, and p, as usual, is $2\,\pi$ times the frequency, or $I=C\,p\,V_1$. This follows at once from equations (19) and (31). The value of the potential difference at the terminals of the condenser, as measured, say, by an electrostatic voltmeter, is therefore determined by the magnitude of the condenser current flowing into it, as measured by a dynamometer when the frequency of the current is known.

12. The writer witnessed some experiments made in the Standardising Laboratory by Major Cardew, in which the above measurements were carried out. A condenser of ·5 microfarad was joined across the poles of an alternator, a Thomson deciampere balance was put in the charging circuit, and a Thomson multicellular electrostatic voltmeter across the terminals of the condenser. The readings of the voltmeter, V_1, and of the ampere balance, I, were taken simultaneously, with the following results:—

Frequency of current, n.	Volts across condenser poles, V_1.	Charging current in amperes, I.	
		Observed.	Calculated.
103	360	·132	·116
103	396	·145	·128
103	493	·175	·160
103	583	·200	·189
90	481	·150	·136
90	598	·187	·170

For the frequency $n = 103$, $p = 2\,\pi\,n = 647$, and for $n = 90$, $p = 565$.

Hence, since the condenser capacity, C, = ·5 microfarad = 5×10^{-7} farads, we have as the values of $C\,p$ for the respective speeds $3{,}235 \times 10^{-7}$ and $2{,}825 \times 10^{-7}$, and the values of the condenser current are calculated from the relation $I = C\,p\,V_1$.

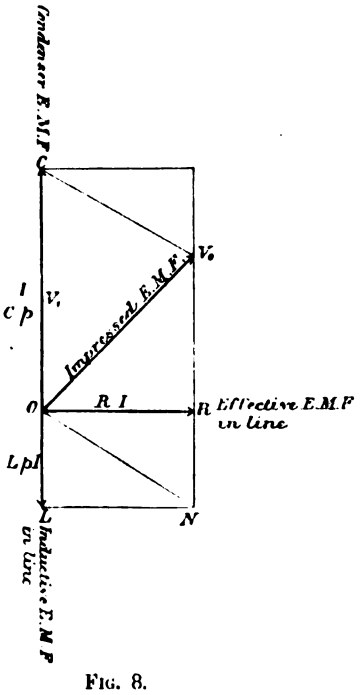

FIG. 8.

The calculated values of the currents are all lower than the observed, and in about the same ratio, viz., about 10 per cent.; but the speeds of the alternator, and therefore the current-frequencies, were not known with a degree of accuracy sufficient to enable it to be determined how far the agreement of observation with theory is complete.

13. The relations between the capacity and self-induction necessary to bring about an increase of pressure at the condenser terminals when an alternator charges a condenser are well displayed by the use of a clock-diagram of electromotive forces. Such diagrams have been given by Mr. Kapp in some recent papers, and the particular one here given is practically the same as one given to me by Major Cardew, who has also examined this particular problem. The following mode of regarding it will be found to be an easy one. Construct a clock-diagram of electromotive forces (see Fig. 8) for the simple case of a condenser charged through an inductive line by a constant harmonic impressed electromotive force. Lines drawn radially from a point, O, in Fig. 8, represent the maximum values of various electromotive forces. Let O V_0 be the maximum value of the impressed E.M.F. at the dynamo terminals, and O C that at the condenser terminals; I the maximum current in the line. Take any line O R to represent the effective

Digitized by Google

E.M.F. in the line, and therefore equal to the product R I, where I is the current charging the condenser, and R is the resistance of the line. From R draw R L at right angles to O R, and let R L be set off equal to $L\,p\,I$; L being the inductance of the line, and p being, as usual, $2\,\pi$ times the frequency of the current. Note that when a quantity varies harmonically the product of p and its maximum value gives us the maximum value of its time rate of change, or time differential, whilst the quotient of its maximum value by p gives us the maximum value of its time integral. Accordingly, O L, which is made equal to $L\,p\,I$, represents the counter electromotive force of self-induction, or back E.M.F., in the line as far as is due to its own inductance, and is in quadrature with R I as regards phase. Hence the resultant of these two is O N. Next set off O C at right angles to O R, and in advance of it, and make O C equal to $\frac{I}{C\,p}$, that is, to the maximum value of the quotient of the time integral of the charging current by the capacity of the condenser. This gives us the counter electromotive force of the condenser, or the E.M.F. at the terminals of the condenser, V_1. We have then to take the resultant of this last and O N, which gives us $O\,V_0$, and this last resultant is the impressed electromotive force at the dynamo terminals.

It is necessary to bear in mind that the counter electromotive force, O C, at the terminals of the condenser is in quadrature with the current flowing into it, and in advance of it in phase. The diagram shows us at once that the pressure, $V_0 = O\,V_0$, at the terminals of the dynamo may be less than, equal to, or greater than the pressure, $V_1 = O\,C$, at the terminals of the condenser; and that this is determined by whether the length of the line, $O\,V_0 = \sqrt{O\,R^2 + V_0\,R^2}$, is greater or less than O C. We see that $V_0\,R = O\,C - O\,L = \frac{I}{C\,p} - L\,p\,I$, and hence that O V_0 is equal

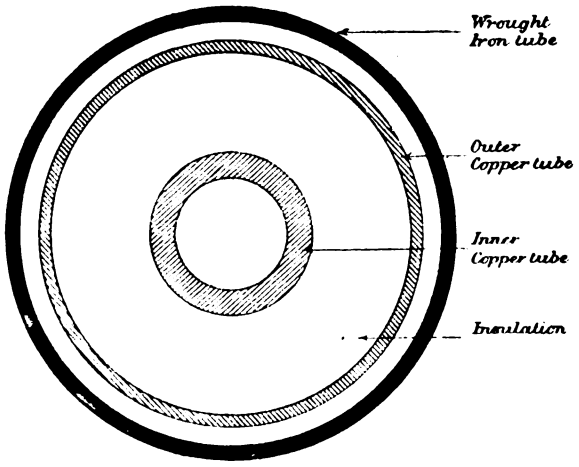

Fig. 9.—Section of Ferranti Trunk Main—Full Size.

to the square root of $\left\{ R^2 + \left(\frac{1}{C\,p} - L\,p\right)^2 \right\} I^2$. Hence the maximum value of the charging current, I, is given by the value of

$$\frac{C\,p\,V_0}{\sqrt{R^2\,C^2\,p^2 + (1 - C\,L\,p^2)^2}}$$

Also we have the same quantity given by the relation $I = C\,p\,V_1$; hence the ratio of V_0 to V_1 is given by the value of the quantity $\sqrt{(1 - C\,L\,p^2)^2 + C^2\,R^2\,p^2}$, as we have already seen analytically. The clock-diagram has the advantage that it shows us at once the various lags, and gives explicitly to the eye a proof that a gradual increase in the value of the inductance, L, from zero upwards is accompanied by a progressive decrease in the value of the terminal pressure, V_0, at the dynamo, as compared with the terminal pressure, V_1, at the condenser.

14. In the next place, I wish to place before you an analysis of some experiments which have been made on great lengths of the Ferranti trunk mains between London and Deptford, and which illustrate these principles in a remarkable manner. We are all aware that these cables are concentric cables, and that they possess, accordingly, very measureable electrostatic capacity. The following are the data of the dimensions of these cables, kindly given to me by Mr. Ferranti. The inner conductor, or inner member, is a copper tube (see Fig. 9) of which the inside diameter of cross section will be called D_1, and radius R_1, and the outside diameter D_2, and radius R_2. The outer conductor, or member, is a copper tube of which the inside diameter will be called D_3, and radius R_3, and its outside diameter D_4, and radius R_4. The insulation between the inner and outer members is compressed brown paper and black wax. The values of the diameters and radii of cross section of these tubes are as follows (see Fig. 7):—

$D_1 = \frac{9}{16}$ of an inch = ·5625 in.
$D_2 = \frac{13}{16}$,, ,, = ·8125 ,,
$D_3 = 1\frac{37}{64}$,, ,, = 1·8437 ,,
$D_4 = 1\frac{15}{16}$,, ,, = 1·9375 ,,

Hence we have—

$R_1 = $ ·281 in. $\quad R_1^2 = $ ·0789
$R_2 = $ ·406 ,, $\quad R_2^2 = $ ·1648
$R_3 = $ ·922 ,, $\quad R_3^2 = $ ·8500
$R_4 = $ ·969 ,, $\quad R_4^2 = $ ·9389
$R_2^2 - R_1^2 = $ ·0850 ,, $\quad R_4^2 - R_3^2 = $ ·0889

Area of cross section of inner member $= \pi\,(R_2^2 - R_1^2) = $ ·2689 sq. in. = $\frac{1}{4}$ sq. in., nearly.

Area of cross section of outer member $= \pi\,(R_4^2 - R_3^2) = $ ·2793 sq. in. = $\frac{1}{4}$ sq. in., nearly.

Also, we have—

$$\frac{R_3}{R_2} = 2{\cdot}270 \qquad \frac{R_2}{R_1} = 1{\cdot}444 \qquad \frac{R_4}{R_3} = 1{\cdot}051,$$

$$\frac{R_1^2}{R_2^2 - R_1^2} = {\cdot}9185, \qquad \frac{R_4^2}{R_4^2 - R_3^2} = 10{\cdot}561,$$

$$\frac{2\,R_1^4}{(R_2^2 - R_1^2)^2} = 1{\cdot}6872, \qquad \frac{2\,R_4^4}{(R_4^2 - R_3^2)^2} = 223{\cdot}068,$$

$$\log_e \frac{R_3}{R_2} = \log_{10} 2{\cdot}27 \times 2{\cdot}3026 = 2{\cdot}3026 \times {\cdot}35603.$$

These quantities are required in the calculation of the inductance of the cable.

If the specific inductive capacity of the dielectric were a definitely known quantity, it would be, of course, easy to calculate from the above figures the capacity of one mile run of the cable by the formula,

$$\text{Capacity in electrostatic units} = \frac{K\,l}{2\,\log_e \frac{R_3}{R_2}},$$

K being the specific inductive capacity, and l the length; and to reduce this to farads by multiplication by $\frac{1}{9 \times 10^{11}}$.

In default of information to enable this to be done, the electrostatic capacity of one length was measured directly by comparison with a standard half a microfarad.

On December 5th, 1890, Mr. Ferranti placed at my disposal two lengths of the trunk mains running from Trafalgar-square to Blackfriars, for the purpose of measuring the capacity. The length of cable used was 2,399 yards, or 1·363 statute miles. The capacity of one of these lengths (No. 3 cable) was found in the usual way (taking the capacity between the inner and outer members) to be ·5 microfarad for the whole length, or at the rate of ·367 microfarad per statute mile. It follows from this that the specific inductive capacity of the material used is about 3·4 (air = 1). Using the other cable (No. 4), the copper resistance was found to be ·324 legal ohms, or ·328 B.A. units per statute mile, reckoning the resistance per mile run of the cable, and including, therefore, both the inner and outer conductor. The insulation resistance between the inner and outer member of the first cable was found to be at the rate of 720 megohms per mile. The instruments used in taking these measurements were a half-microfarad condenser by Dr. Muirhead, and a legal ohm Wheatstone bridge and megohm standard, kindly lent by Messrs. Elliott Bros. for the purpose. The temperature of the ground on that day was near the freezing point, and Nature saved us the trouble of reducing the values to zero centigrade.

The remaining element required is the inductance of the cable per mile. Fortunately, the form of cable which is the best for practical reasons is almost the only case in which the inductance can with no great difficulty be calculated with any required degree of accuracy from the dimensions of the cable. Lord Rayleigh has solved for us the problem of the inductance of a pair of concentric conductors placed co-axially. His formula, as given in his Paper in the *Philosophical Magazine* of May, 1886, p. 385, is as follows, when translated into my nomenclature, and the values of the magnetic permeabilities of the materials all taken as equal to unity:—

$$L = \text{inductance per unit of length} = 2 \log \frac{R_3}{R_2} + \frac{2}{R_2^2 - R_1^2}\left(\frac{R_2^2 - 3\,R_1^2}{4} + \frac{R_1^4}{R_2^2 - R_1^2} \log \frac{R_2}{R_1}\right) + \frac{2}{R_4^2 - R_3^2}\left(\frac{R_3^2 - 3\,R_4^2}{4} + \frac{R_4^4}{R_4^2 - R_3^2} \log \frac{R_4}{R_3}\right).$$

Digitized by Google

The logarithms are all Naperian, and the values of R_1, R_2, R_3, and R_4 may be taken in any units, as only their ratios are required.

The values of the chief functions of the radii of the tubes have been given above, and, making the substitutions, we have for the inductance of one centimetre run of the cable the following value:—

$$L = 2 \log 2{\cdot}27 + 1{\cdot}6872 \log 1{\cdot}444 + 223{\cdot}068 \log 1{\cdot}051 - (9185 + 10{\cdot}561).$$

Remembering that the logarithms here are Naperian, and that the logarithms to base 10 must be multiplied by 2·3026 to reduce them to the Naperian base, we have as a final result of the calculation,

$$L = 1{\cdot}7755 \text{ centimetres.}$$

Hence, since one statute mile = 160,931·5 centimetres, the inductance per statute mile of the Ferranti cable is 285,734 centimetres = ·0002857 of a henry, or 285·7 microhenrys.

This result will be accurate to just the extent to which the diametrical measurements of the conductors are accurate.

Collecting our results, we have for one statute mile run of the Ferranti trunk main the following values, as deduced from measurements on the particular lengths employed:—

R = Copper resistance at 0° cent. of lead and return ..... = ·324 legal ohm per mile.

K = Insulation resistance of length measured at rate of ..... = 720 megohms per mile between inner and outer conductor.

C = Electrostatic capacity between inner and outer conductor ..... = ·367 microfarad per mile.

L = Inductance ..... = 285·7 microhenrys per mile.

The formula given above for the inductance per unit of length can be applied to stranded concentric cables with a fair degree of approach to accuracy.

Suppose that we are sending periodic currents having a frequency of 67 through the Ferranti cables, then, if n = frequency = 67, $2\pi n = 421 = p$, and $4\pi^2 n^2 = p^2 = 177{,}241$.

Hence, since R = ·324 ohm, and L = ·000286 henry, we have $\sqrt{R^2 + p^2 L^2} = {\cdot}3455$ ohm for the impedance per mile, and we see that at this frequency the impedance exceeds the resistance by about 7 per cent. of the latter.

From the data thus given other functions of the capacity, C, inductance, L, resistance, R, and impedance, I, per mile can be built up, which will be required presently. These are—

$$P^2 = \frac{C p}{2}\left\{\sqrt{R^2 + p^2 L^2} - p L\right\} = {\cdot}00001738;$$

$$Q^2 = \frac{C p}{2}\left\{\sqrt{R^2 + p^2 L^2} + p L\right\} = {\cdot}00003597.$$

Hence, also,

$$P = {\cdot}004168,\ Q = {\cdot}005997;$$

$$P^2 + Q^2 = {\cdot}00005335,\ \frac{P^2 + Q^2}{I^2} = \frac{447}{10^6};$$

$$(2 P R + 2 Q L p) = {\cdot}004147;$$

$$(2 P L p^2 - 2 Q p R) = -1{\cdot}216.$$

All the quantities refer to one mile run of the cable.

(To be continued.)

SOME RESEARCHES IN ELECTRO-MAGNETIC INDUCTION.*

BY E. B. VIGNOLES.

The subject of electro-magnetic induction is one whose ramifications extend into almost every commercial application of electricity. I need, therefore, little excuse for bringing before you to-night a short account of an investigation into induction phenomena which, even if it traverses somewhat well-trodden ground, presents some novel features of method and application which may perhaps repay your attention.

Before proceeding to describe to you the method used by Mr. Evershed and myself in these investigations, I may perhaps briefly state the circumstances which led to our undertaking the research. When we started our experiments some two years ago, the subject of transformers was being much discussed; and as we, in common with most other people, were rather hazy in our ideas concerning the actions of this convenient but perplexing machine, we determined to investigate these actions from the beginning by determining, *de novo*, the magnetic properties of closed rings of various materials. The method of drawing the actions of a transformer as described in Mr. Evershed's Papers in *The Electrician*, was then in process of conception, and he saw that these curves were the one thing needful. We knew, of course, that Ewing and Hopkinson had already published similar curves, but their Papers are somewhat inaccessible, and their methods seemed to us open to some objections, objections of which I will treat further on.

But before I proceed to further describe the methods used, it may be as well, since the nomenclature of magnetic phenomena is in a somewhat amorphous condition, to describe the sense in which various terms will be used in this Paper.

The first thing that we have strongly set our faces against is the use of the term "induction" in the sense of "induction density." It is as if we had no term for current, and used current in the sense of current density. It simplifies one's nomenclature to call **B** × area "the induction," just as in the case of current; and to call **B** the "induction density," and I shall take the liberty of doing so in this Paper.

I shall not allude to "I," for the good reason that I can form no conception of what it means physically. I fancy it is something to do with the induction density that would have been present in an electric circuit if the iron which is there wasn't there! It seems useless to make such artificial distinctions, and I follow Dr. Hopkinson's distinguished example in treating of nothing but **B**, **H**, and μ.

The remaining point as regards nomenclature is the abuse of the term "lines of force." As expressing the direction in which the induction acts at various points, they have an obvious and valuable use; but these lines do not increase or diminish as the induction becomes greater or less. Whether you have 10^{-10} or 10^{+10} units of induction, the lines of force remain precisely the same. They should be symbols of *direction* and not of *quantity*. The use of the term "lines of force" for units of induction, not only leads to false mental pictures, but it is clumsy. We were, therefore, compelled to invent a new unit for induction, as no one else had done so. This unit was born some two years ago, and was christened the "thom," after our leading electrician. It serves its purpose: you can speak of a "thom" without committing yourself to anything, or thinking of anything in particular.

The Paris Congress has adopted a unit of induction density called the Gauss. It is really an unnecessary unit, as "Thoms per sq. cm." is all that is required; but it is convenient, and we have always used it. It simplifies the numbers on the curves of **B** and **H** to call 1,000 gausses, a "kilo-gauss" in the usual metric manner; and I have done this in my tables and curves, where **H** is in dynes, and **B** in "kilo-gausses."

Having thus explained my use of terms, let us return to the consideration of the action of iron in transformers.

The importance of imitating as closely as possible the action of the magnetising current in a transformer strongly impressed us. We saw that it was necessary, when investigating any induction cycle, to carry the iron through that cycle before every observation, and always to start from one extremity of the cycle.

It may be said that the ordinary method of procedure, by reducing the current from the negative maximum by jumps to O, increasing to the positive maximum in the same way, and then reversing the process, noting at each jump the throw of the ballistic galvanometer, is equally good; but this is not so, for in a transformer you are not stopping anywhere on the force-induction curve, except at the positive and negative maxima. It might happen that the iron behaved differently in the two cases; and we know from Ewing that the induction has a tendency to creep up under the prolonged action of a magnetising force.

Magnetometer methods were out of the question, for iron rods do not behave like closed rings, unless, according to Ewing, their length is about 400 times their diameter. As we wished to experiment on masses of iron, and not on wires, which might, and in fact do, behave very differently, the minimum diameter we could have used would have been half an inch. This makes our rod 18 feet long, which is somewhat alarming.

Hopkinson's method is a very handy and convenient one, but the fact that it introduces other material than the one under test, and that at least two, and generally three, joints are necessary parts of the magnetic circuit, is a great disadvantage. It may be that a very small portion of the magnetising force is spent on the "return" block, but still there is always something; and that something is rendered somewhat indefinite by the hysteresis of the block. This amount may, however, be indefinitely reduced by making the block big enough, but it is not so with the joints. It will always take an appreciable percentage of the magnetising force to push the induction through these joints, and this percentage will vary in every sample of iron tested owing to minute differences in the tightness of the joint. It will be noted that since the bar has to be pulled out suddenly, the joint with the block can never be

*A Paper read before the City and Guilds of London Institute Old Students' Association, May 13, 1891.

Digitized by Google

made really very tight A modification of this method using very ght joints, and winding with wo primaries (as in our method) to avoid having to pull out the test bar, might have its advantages; for it would no longer be necessary to wind each sample of iron, which is of course essential in the ring method, and it saves one joint; but turning the bars would entail nearly as much work as winding a ring, and work of a more expensive class, for any boy can wind one of our rings properly, but accurate turning would require more skilled labour. Thin laminæ of iron, as used in transformers and armatures, cannot be tested by this method, which practically puts it out of the question.

The most important experiments performed by means of rings, according to Kirchhoff's method, are those of Bosanquet. He, however, did not, as far as I know, take hysteresis curves, but confined himself to average curves, obtained by means of the reversal method. For testing iron where the amount of coercive force is not required this method is excellent, and many of our curves have been thus obtained.

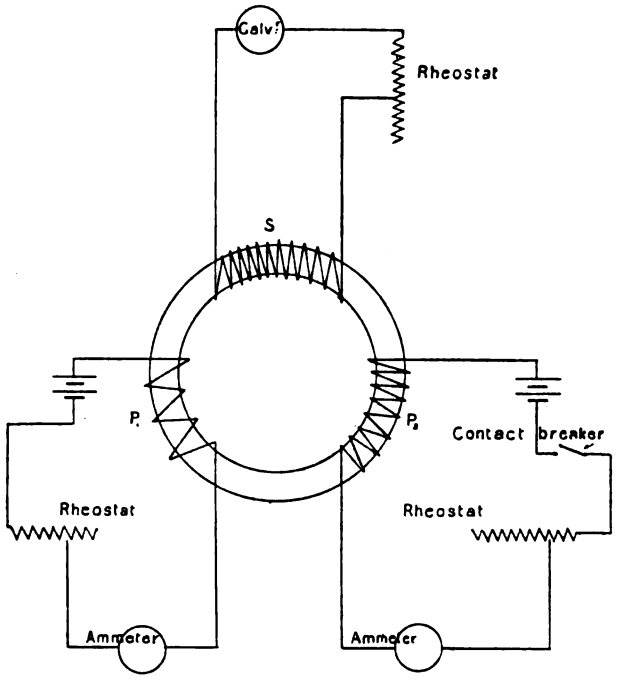

FIG. 1.—Arrangement of Apparatus for Testing.

To obtain the hysteresis curves, and to ensure the conditions being the same as in a transformer—that is to say that the magnetising force must always be carried from one extremity of the cycle to the point under observation at one fell swoop—we adopted the following method of winding.

The rings are generally about 13 cm. in diameter, and one or two sq. cm. in area; they are wound continuously all round with two primary coils, P_1 and P_2, and a secondary S is wound on, generally over the primaries for convenience, to produce the galvanometer deflection. One primary has preferably twice the turns of the other; in any case the currents must be so arranged that at the maximum the ampere turns on P_2 are twice those on P_1.

The arrangement of the circuits is shown in Fig. 1, where the coils are drawn separately for the sake of clearness; they really are wound over one another.

P_1 has say n turns, P_2 has $2n$ turns.

A current of some definite value, so arranged that the total magnetising force is of the dimensions required to keep the iron at the end of the cycle to be investigated, is kept up constantly in P_1; thus holding the iron at the negative maximum (0, Curve 1), when P_2 is not in action.

When a current of the same value, but in the opposite direction, is flowing in P_2 the iron is carried to its positive maximum, since P_2 has twice as many turns as P_1.

The mode of obtaining the curve is now obvious. Let Curve 1 represent the cycle under investigation. The "fiducial current" in P_1 is say 10 amperes; this current remains on all the time the cycle is being obtained, and is kept always accurately at the same value.

10 amperes are then put through P_2 in the reverse direction, and then broken; carrying the iron to the positive maximum, and returning to 0, the fiducial point.

The observation is then made by making a small current in P_2 (thus reducing the net ampere turns), and noting the deflection of the ballistic galvanometer. The ordinate A B is thus obtained.

The iron must then be again carried to the positive maximum, and back to O, by making and breaking 10 amperes in P_2.

The next point is obtained similarly, by making a somewhat larger current in P_2; this gives the ordinate C D.

Note that any observation can be repeated at once, which is often necessary, and which is impossible by the ordinary method.

Similarly the whole rising curve is obtained, the iron being put through its cycle between each observation, to remind it that it is a transformer.

The falling curve is of course similar, and may be obtained by reversing the currents in both coils.

Now, if this curve is obtained in the ordinary manner by successive jumps, first from O to A, then from A to C, and so on, the iron has time between successive observations to creep up along the curve from A to A' say, and the ordinate E' C is obtained at the next jump instead of E C. The sum of the deflections is then not great enough. Also the quantities passing through the galvanometer are not as great as they are in our method, and consequently the chances of error are greater.

Curve 1 is a curve obtained by our method, which shows its extreme value in the steep parts of the curve. Table 1 gives the actual values of the B and H (the induction density in kilo-gausses, and the magnetising force per centimetre of length in dynes), obtained by observation, and it will be noticed that even in the steepest parts the curve can be traced with absolute certainty, every observation being exactly on the curve.

It has been asserted that the induction is unstable at the steep part of the curve; this is not so, as far as masses of iron are concerned, for we have never had any difficulty in stopping at any part of the curve and reproducing an observation. In connection with this subject of instability, I may mention another point which

Digitized by Google

is noticeable. Prof. Ewing found that the residual induction in his soft iron wires was very unstable ; so much so, that a man walking in an adjoining passage caused enough vibration to shake all residual induction out. Mindful of this, we carefully tested our early rings for this effect ; while Mr. Evershed held the galvanometer switch over, I gently stroked the ring—nothing happened ; I tapped it lightly—still nothing. I ended by smiting it with a hammer, under which severe treatment it yielded up—2 per cent. of its residual induction! We concluded, therefore, that it required considerable *molar* vibration to affect masses of iron. It is not so with *molecular* vibration. A very small force applied by means of an electric current, either in the direction of the induction or at right angles to it, shakes out all residual induction.

There are two errors which must be looked for in all methods of measuring induction. First, air induction in the secondary, if it is larger in area than the iron ; this becomes of importance when the permeability of iron comes down near that of air, but may be neglected in most cases for small cycles, or calculated and allowed for. Secondly, unsymmetrical winding of the primary or primaries. We found that if a primary be wound half round a ring about 4in. across, 10 per cent of the induction leaked across through the air from end to end of the coil ; thus H cannot be calculated, owing to the unknown distribution of the magnetising force.

The advantages of the method described being so many, we finally decided to adopt it : and proceeded to manufacture our apparatus.

The ballistic galvanometer, of which details are given in Table II., appears to the naked eye a rough piece of apparatus, but it has performed its work admirably, and has never given us any trouble.

Table II.—*Ballistic Galvanometer.*

Length of needle = 4·8 cm. Sect. area = ·0726 sq. cm.
Period = 3·8 seconds.
Resistance = 69·6 B A ohms at 20°
Max. angle of deflection = 9°

My audience must remember that all these experiments were carried out in engineering works, and not in a laboratory ; and this fact made us anxious to eliminate every source of error. We had to devise a ready method of standardising the galvanometer every time we used it, as motors and dynamos in the immediate neighbourhood are not conducive to constancy in the earth's field.

We therefore made a solenoid of length 120 cm. and diameter 3 cm. Its length being great compared with its diameter, the field at its centre could be accurately calculated, from the well-known formula

$$\mathbf{H} = \frac{\cdot 4\pi C N}{l}$$

where C is current in amperes, N the number of turns, and l the length.

Assuming that the permeability of the broomstick on which the solenoid was wound to be the same as that of air

$$\mathbf{H} = \mathbf{B}$$

we thus get the number of Thoms per unit of area at the centre of the coil.

The secondary, wound inside the solenoid in a groove in the broomstick, had 1,000 turns of very fine wire. Its average area was 5·0 sq. cm.

$$\mathbf{H} \times \text{area} = \frac{\cdot 4\pi C N}{l} . a$$

gives the induction cutting the secondary.

This broomstick standard thus gives us a means of calibrating our galvanometer as well as standardising it.

The theory of the ballistic galvanometer given in text books says, that the induction is proportional to the throw, under certain conditions, one of which is that if there is damping, corrections must be made by means of a "logarithmic decrement." We did not quite know what a logarithmic decrement was, and so we preferred to try whether our scale was a straight line, by going to the *fons et origo* of all knowledge, experiment.

$$\theta \propto \frac{1}{R}$$

if $\mathbf{B} \times$ area is kept constant ; where θ is the throw, R the resistance of the circuit, and B the induction density. Then we took a curve of B and θ for constant resistance and turns, and this curve cannot be distinguished from a straight line.

If, therefore, all deflections are taken with the same resistance in circuit, the formula is

$$\theta = \frac{a n}{R} (\mathbf{B} \times \text{area})$$

where a is a constant depending on the galvanometer.

Owing to the variation of the amount of damping with the resistance of the secondary circuit, this formula is not true (except at the resistance at which the galvanometer was standardised), unless the damping be properly allowed for.

Deflections taken at various resistances can be made comparable with one another, by substituting for them uniformly the value they would have had, if some fixed resistance (infinity for convenience) had been in circuit.

A curve of coefficients, by which throws at various resistances must be multiplied in order to reduce them to "throw on open circuit," is easily obtained.

A fixed impulse is given by means of an external coil by tapping a key, and the deflection noted for open circuit, and for various resistances. The damping increases as the resistance of the circuit decreases, and the percentage difference from the throw at infinite resistance is thus obtained. This curve is shown in Fig. 2. By

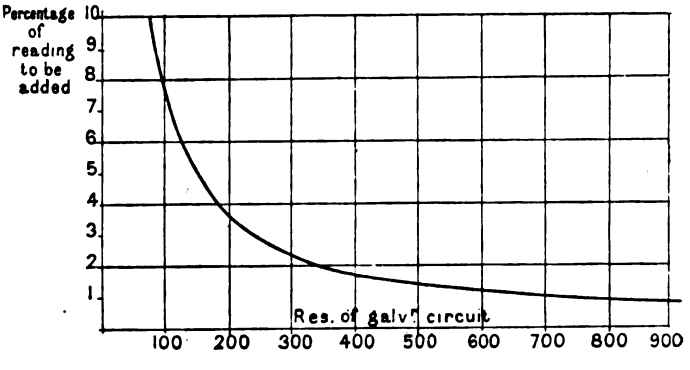

FIG. 2.—Ballistic Galvanometer Damping Curve.

means of it all throws can be reduced to throw on open circuit by multiplying by the required percentage. The curve is a rectangular hyperbola.

We are now prepared to standardise the galvanometer.

Since $$\theta = \frac{a n}{R} (\mathbf{B} \times \text{area}),$$

the induction $= \mathbf{B} \times \text{area} = \frac{R \theta}{a n}$;

whence we see the $\frac{1}{a}$ or g, the galvanometer constant is to be obtained. Now,

$$g = \frac{1}{a} = \frac{R \theta}{n \mathbf{B} \times \text{area}},$$

and thus one deflection from a known B in the broomstick gives the required constant.

Any mutual induction coil may be standardised by means of the solenoid, and used as a standard in place of the somewhat clumsy broomstick.

In our "Mutual Inductioner," 1273 Thoms cut the secondary for 10 amperes in the primary. Everything was now ready, except that all-important item in a research, the elimination of "niggers." I may mention some of these, in case any of you ever have to investigate force-induction curves.

It is necessary to break the primary *very* sharply. We had much trouble from double-breaks until we made a "jumper," in which a copper wire filed to a point was pulled from a mercury cup by elastic. This arrangement is perfectly satisfactory.

Bad contacts in the secondary circuit are a fruitful source of error when working with low resistances. We have made a rocking mercury-cup switch, which when put over to the left, throws the ballistic galvanometer into circuit, and when over to the right short circuits the galvanometer, and puts the remainder of the circuit on to the bridge, so that its resistance can be taken if necessary before or after each deflection, since the resistance alters by heating. To avoid these errors, wind many turns of secondary, so as to have *large* resistances in circuit ; in this case the heating of a secondary of a few ohms does not matter.

A great many errors may be due to the currents in the primary circuit affecting the ballistic galvanometer directly. We leave our leads long, and can then raise, lower, or coil them up, till currents in them do not affect the galvanometer. This point is most important, especially with large primary currents. These "niggers" having been discovered and eliminated, we were in a position to begin our research.

(To be continued.)

LEGAL INTELLIGENCE.

The Jablochkoff Patent.

The resumption of the argument in favour of confirmation and prolongation of the Jablochkoff distribution patent, No. 1,996, of 1877, came before the Judicial Committee of the Privy Council on Wednesday last, the Committee being represented on the occasion by Lord Watson, Lord Morris, Lord Hobhouse, and Lord Shand.

The Attorney-General (Sir Richard Webster) and Mr. Sutton appeared for the Government to oppose the petition. Mr. Moulton, Q.C., who had the petitioner's brief, being ill with influenza, the petitioner's counsel were Mr. Roger Wallace and Mr. Renton.

The application of the petitioner, it will be remembered, was for a confirmation and extension of time for his patent.

The ATTORNEY-GENERAL said it was his duty to oppose both the petitions. The general grounds of his opposition had been submitted to the Court, but there was one point he was not in possession of at the last occasion. By paragraph 4 of the petition it was shown that Mr. Jablochkoff obtained patents in France, Belgium, Germany, Italy, and the colony of Canada for the same subject-matter of invention, but the dates of those foreign patents were not stated. The Attorney-General said he found that some of those patents were taken out prior to the date of the English patent. On May 22, 1877, there was a patent issued in England, but on November 30, 1876, there was the French patent—that was to say, a year and nine months before the English patent. That French patent was alleged to be still in force, but he was informed it would expire in November of this year. Then the Belgian patent was also taken out before the English patent—viz., on February 6, 1877, and which expired on October 8, 1888. He would have to refer, on the merits, to two others—one taken out in Germany on August 14, 1877, and which lapsed in 1883; and the other taken out on May 25, 1877, or three days after the English patent, which also lapsed in 1883. He did not especially refer to those two at that moment, though he thought they brought a serious difficulty in the way of his learned friend (Mr. Wallace). Their Lordships would be aware that the petitioner was proceeding under the repealed statute of 1883, by virtue of the saving clause. If their Lordships would look at section 25 of the Patent Law Amendment Act of 1852 they would see that where an earlier patent was taken out in a foreign country, and was allowed to expire, the English patent died with the same period. Therefore, unless his learned friend had some answer, based on the Act of 1883, that was a fatal objection so far as the Belgian patent was concerned. Continuing, the learned gentleman said the only point for the petitioner could be that, because the Belgian patent did not expire till 1888, the Act of 1883 having repealed the earlier statute, therefore the bar was not total in that case; but, by anticipation, he was obliged to submit that that could not be an answer.

Mr. ROGER WALLACE (for the petitioner) said he did not dispute the cases his learned friend had read, so far as the patents to which they applied. He did not dispute that the foreign patents were taken out before the date of the English application, so that he could not argue that he came within the wording of the 25th section of the broad Act, 15 and 16 Vict., c. 83. But he did submit that the Act of 1883 did preserve to the petitioner the right of claiming the benefit of confirmation of his letters patent, and that the objections before the Act of 1883 did not apply.

After a long argument the room was cleared for their lordships to confer.

JUDGMENT.

Lord WATSON delivered the judgment of the Committee as follows:—There are two separate applications in regard to this patent; in one their Lordships are invited to recommend that the patent be confirmed under the terms of the second section of the Act 5 and 6 William IV., c. 83; and in the other to recommend the prolongation of the patent for such term as shall seem to them to be just. The English patent bears date May, 1877, but in the same year at a previous date, viz., on February 6, 1877, the same invention was secured to the patentee in Belgium. And that right or privilege was declared to have lapsed by the Royal decree on October 8, 1888. It is conceded in argument by the petitioner that no application for confirmation of patent can be made under the Act of 1883, and that statute abolished the Act of William already referred to, but the Board are still in a position to entertain petitions for confirmation by virtue of the provisions of the 113th section of the statute, which saves a portion of the Act in so far as it relates to patents which were in force at the time when the statute of 1883 became law. If the Act of William stood alone, the case of the petitioner would be comparatively plain, but the powers of confirmation which were conferred by the statute were qualified by the Patent Act of 1852, the 25th section of which enacted that in the case of an English patent, where a previous patent for the same invention had been taken out in a foreign country, the patent should cease, and be void immediately upon the expiration or other determination of the term during which the patent or legislative privilege obtained for such foreign country shall continue in force. If that qualification still applies to the right—the patent right—of the petitioner, there is an end of this case, because his patent lapsed in 1888 along with the Belgian right, in the terms of the statute. But the argument that has been addressed to their Lordships has been to this effect—that whilst section 25 of the Act of 1852 is wholly repealed in so far as regards this patent, section 2 of the Act 5 and 6 William is kept alive in his favour. Now that is founded upon the provisions of the sub-section 1 of section 113 of the Act of 1883, which appears to their lordships on consideration to be fatal to the contention addressed to them. The saving clause in favour of the patent in force at the date of the statute is in these terms. In section 1 it is declared that the repeal of the previous enactment shall not date to the past operation of this enactment for any patent, or right, or privilege, or obligation, or liability acquired, approved, or confirmed under any enactment before or at the commencement of the Act. Now it appears to their Lordships that at the date when the statute of 1883 was passed there was, incidental to the right of the patentee or his assigns in possession of the capital before us, first a right to confirmation, should it be necessary, under the Act of William; but in the second place a liability on their right, to be determined in the event of the lapse of the Belgian patent. These were a right and a liability which had arisen and formed part of the law of patents at that date. And it certainly does appear to their Lordships that, looking at the language employed by the Legislature, which saves all obligations and all liabilities attaching to the patent, as well as all rights to the patentee, it is impossible for them to affirm that the Legislature meant to retain to the patentee his rights where older than the statute, and right to confirmation, without a corresponding qualification introduced by the legislation of 1852. And, therefore, it appears to them that the petitioner here cannot appeal to the provisions of the Act 5 and 6 William IV. without submitting at the same time to the qualifications of the statutory rights there introduced by the Patent Act of 1852. Therefore the application must be dismissed.

There remains the petition for extension of the patent, which may be very shortly dealt with. As regards the application, the petitioners are in this dilemma—that if it be presented as a petition, presented in terms of the recent Act, the answer is conclusive—that the statute does not apply, because it was not presented more than six months before this natural currency of the patent came to a close. And the other alternative is that it is an application under the old law; and if it is an application under the old law, the provisions of the 25th section of the Act of 1852 are as fatal to the power of this Board to deal with extension as those provisions were fatal to the application for confirmation. Therefore this petition must also stand dismissed.

In re Institute of Medical Electricity.

Mr. JUSTICE CHITTY, on Wednesday last, dismissed a petition for winding up this Company.

Mr. Byrne, Q.C., and Mr. Le Breton appeared for the petitioner; and Mr. Farwell, Q.C., and Mr. Lawson for the Company.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May* 1, 1891.

Edison Slow-Speed Tramcar Motors.—At last the much-heralded Edison slow-speed street car motor has put in an appearance, and so far as can be judged from rather complete descriptions, it is possessed of no strikingly valuable characteristics, or unusual details. It is a four-pole machine of ironclad form, having a large Gramme armature. The pattern is not widely different from that of the Wenstrom-street railway motor, but, so far as can be judged from appearances, the amount of iron employed is very scanty considering the fact that the field magnets are castings. The two salient poles are of dubiously small cross-section, and the magnetising coils T-shaped, very flat, and of dimensions that bespeak danger of heating. The armature is a Gramme ring 18in. in diameter and 13in. on the face, built up of soft iron stampings, supported on a aluminium bronze spider. The armature is wound with a continuous wire, and its principal peculiarity is that the leading wires to the commutator are made of German silver. This is said to be for the purpose of reducing the induced current where the brushes are short circuited, and hence diminishing sparking. Inasmuch as a properly constructed motor shows no appreciable sparking from this cause one is led to the conclusion that either the advantage gained is purely fanciful, or that the motor possesses electrical characteristics such as render something of the sort absolutely necessary. The armature spindle has a pinion at each end, meshing into the gears on the car axle, so that, although there is but a single reduction speed by gearing, the same number of wheels to wear and rattle are provided as in the old Edison motor. The wearing, of course, is somewhat diminished, but the gears are there. Another peculiarity of the new Edison machine is the use of four carbon brushes, a feature that hardly commends itself to the practical street-car man, and seems totally unnecessary in the present state of electrical designing. The speed of the new motor is reasonably slow, about 460 revolutions per minute, at a car speed of 12 miles per hour. The method of regulation employed is the same as that which has displayed its virtues and vices in the old Sprague motor. Each of the two magnetising coils is divided into three sections, which are commutated by a switch box similar to that the Edison Company has previously used. Altogether the new machine is somewhat disappointing. It looks as though the

Digitized by Google

field coils are likely to be worked rather harder than is conducive to long life. The resistance of the motor is judiciously not stated.

The Westinghouse Company.—The annual meeting of the Westinghouse Company will be held next Monday, and then the public will probably know something about its financial status. From all appearances the Company has, through the efforts of Mr. Westinghouse, been extricated from its difficulties quite successfully, and will prove no small factor in the construction work of the coming season. The railway department proposes to push the Westinghouse gearless motor very actively, and a few weeks will probably see roads equipped on this system under actual operation. What with the coming gearless and single-reduction-gear motors electric traction work during the summer will be of unusual interest. These new machines have only been tried in a somewhat limited experimental way, and it will probably take some bitter experience to bring them into first-class working condition. There is a tendency to work copper altogether too hard in the attempt to secure low speed, and it is not unlikely to cause breakdowns in some of the early roads. Still, the gearless or singly geared motor is sure to come, and eventually it will crowd out the older forms; but these types are likely to be perfected only through actual experience.

CORRESPONDENCE.

THE CITY AND SOUTH LONDON RAILWAY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Everyone connected with the electrical profession wishes well to the City and South London Railway, and I therefore wish to give the management a hint, which may have more effect if given through your columns than if sent direct, and which, if acted on, will, I feel sure, save them claims for damages.

I refer to the lighting of the stairs leading to the trains. At the Monument and Stockwell this is fairly adequate, but at the intermediate stations—the Oval, for example—the lighting is altogether insufficient. Going in from the bright sunlight, the greater part of the stairs appear to be absolutely dark, and one has to grope one's way with the utmost care to avoid a serious fall. Being spiral, the stairs require a number of lights, and the fact that they are spiral makes them all the more dangerous.

Then, again, sir, can nothing be done to improve the lighting of the carriages? At present it is most tantalising to anyone trying to read. Sometimes the light vanishes entirely, while every now and then it drops to a dull glow, making reading impossible. It should surely not be beyond the resources of science to apply the electric light satisfactorily to railway carriages on an electric railway.—Yours, &c., R. N.

TRADE NOTES AND NOTICES.

"THE ELECTRICIAN"

ELECTRICAL TRADES' DIRECTORY & HANDBOOK for 1891.

The 1891 edition of our well-known Directory and Handbook is ready, price 5s., postage extra. The book consists of over 900 pages, and has entailed this year a heavy amount of work. The HANDBOOK DIVISION contains a mass of most useful information. The DIRECTORY DIVISION consists of 430 pages, and contains a very carefully compiled Alphabetical and Classified List of Firms and Persons engaged in the Electrical and Allied Trades in all parts of the world. This Division has been corrected up to date, and the book is thoroughly reliable, the very numerous changes which take place at the beginning of the year being incorporated. By the aid of this Directory, makers of Electrical Machinery, Apparatus, Instruments, Fittings, Sundries, Novelties, and other goods, may safely communicate direct with probable customers without the annoyance and great expense consequent upon using books which are mere lists of Members of Scientific Societies repeated again and again. The Colonial and Foreign Division of this Directory will be found extensive and reliable. *Orders should be forwarded at once.*

In the course of a few weeks "The Electrician" Company will publish "THE ELECTRICIAN" PRIMERS in two volumes, price per volume 2s. paper covers, 2s. 6d. cloth.

TENDERS INVITED.—The Romford Local Board of Health invite tenders for lighting the public lamps by electricity, gas, or other illuminant; as to a portion (123), during a period from August 10th next to June 10, 1892; and for a further portion (10) for 12 months from September 1st next. Tenders, which should include cost of lighting, cleaning, and repairing, should be sent in to Mr. A. W. Hunt, the Clerk to the Board, on or before 4 o'clock on Monday, June 1st. Some further details will be found in our advertisement columns, and full particulars may be obtained on application to the Surveyor of the Board.

——— Tenders are invited by the Gas Committee of the Manchester Town Council for the lighting by electricity of the Town Hall. Tenders are to be divided under two heads—(1) To supply and fix the whole of the fittings and all necessary connections and appliances required to light the various rooms and corridors; (2) To supply and fix the motive power, such as gas engines, dynamos, and all plant, &c., necessary for the production of the electric light. The rooms, &c., to be lighted will be pointed out on application to the Steward. Further particulars may be obtained from the Town Clerk, and tenders, addressed to the Chairman of the Gas Committee, must be delivered at the Town Hall by June 17th.

——— The Clevedon (Somerset) Local Board are, as will be seen by our advertisement columns, desirous of receiving tenders for the public lighting of their district for one, two, or three years; and tenders are to reach Mr. H. C. Fry, the Clerk, on or before June 2nd.

——— Mr. Dun. Cameron, architect, of Inverness, invites specifications and tenders for the electric lighting of Corrimony Mansion House, Glen-Urquhart, Inverness-shire. Particulars will be found in our advertisement columns.

——— The Barnet Local Board invite tenders for lighting their district for terms of three, five, or seven years. Particulars may be obtained of Mr. H. W. Poole, Clerk, 18, High-street, Barnet, to whom tenders are to be sent not later than the post first on May 19th.

——— The Directors of the Great Eastern Railway Company are prepared to receive tenders for the supply of telegraph materials, india-rubber, &c. Patterns may be seen at the Stores, Stratford. Forms of tender are to be obtained at the Secretary's office, Liverpool-street Terminus, E.C., where tenders are to be forwarded on or before 10 a.m. on May 23rd.

ELECTRICAL ENGINEERING CORPORATION (LIMITED) (IN LIQUIDATION).—Claims against this Corporation must be forwarded to the liquidator, Mr. F. W. Pixley, 24, Moorgate-st., E.C., by June 6th.

MAXIM-WESTON ELECTRIC COMPANY (LIMITED).—Claims in respect of the old Company must be forwarded to either of the liquidators, Messrs. John Marks, 113, Great Russell-street, Bloomsbury, W.C., and Louis Swaby, 23, Churchfield-road, Ealing, and claims in respect of the new Company must be forwarded to either of the liquidators, Messrs. John Marks, as above, and James Hodgson, 17, Little Trinity-lane, E.C.—in each case by May 31st.

WOODHOUSE AND RAWSON UNITED (LIMITED).—This firm sends us particulars and prices of the Epstein accumulator, of which they are the sole manufacturers and suppliers. Accompanying this information are some illustrations and particulars of hydrometers and the W. and R. patent cell tester.

MESSRS. OSBORNE AND CO.—This firm announce that they have started in business at Pleasant-place, Essex-road, London, N., as electrical and chemical engineers. They are bringing out a new form of primary battery.

MAGNOLIA METAL.—In consequence of the largely increased sales of magnolia metal during the past year the Magnolia Anti-Friction Metal Company beg to announce that they are enabled to quote the following cash prices, to take effect May 1, 1891, and until further notice:—For quantities of one ton and over, £112 per ton; 5cwts. and over, 1s. 1½d. per lb.; in less quantities, 1s. 3d. per lb. Magnolia is packed in 46 and 112lb. boxes each.

THE HENRY DRY CELL.—The General Electric Company are bringing out a new dry cell which is made up in two very neat forms, one with a black glass jar, and the other with an oblong composition cell. They are also arranged in boxes for use with small lamps, testing, &c. We hope shortly to give further details as to their capabilities.

ANNUAL DINNER GRATUITIES.—We are pleased to receive from the Edison and Swan United Electric Light Company a note that the Directors have had brought before them the very reprehensible practice of soliciting for subscriptions to their *employés'* annual excursion. The Directors most strongly disapprove of the practice, and they have issued an order, upon the terms of which we congratulate them, that any *employé* of the Company so soliciting will be dealt with summarily, and that firms who supply materials to the Company offering any gift of money or present will be struck off the Company's list. We shall be pleased to extend our congratulations.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

April 21, 1891.

6,906. G. WILKINSON. London. Improvements in arc electric lamps.

April 22, 1891.

6,908. J. MCLAREN. Edinburgh. An electro-magnetic gas controller.

6,963. C. E. SPAGNOLETTI. London. Improvements in means for staying telegraph signal, and other posts or masts.

6,978. A. J. BOULT. London. Improvements in or relating to the automatic regulation of dynamo-electric machines. (William Stone, Australia).

7,009. W. R. WYNNE. Newcastle-on-Tyne. Improvements in electric bells.

7,010. W. R. WYNNE. Newcastle-on-Tyne. Improvements in electrical mining keys, &c.

April 24, 1891.

7,075. E. H. ROYCE. Manchester. Improvements in incandescent electric lamps, holders, ceiling roses, and other like fittings.

7,080. A. WILBAUX. London. Improvements in or connected with the manufacture of wall or other coverings, artificial leather, electrical insulators, boxes, and other articles, from vegetable parchment.

7,085. T. COAD. London. Improvements in portable electric lamps.

April 25, 1891.

7,126. H. JENSEN, J. JENSEN, and WOODHOUSE AND RAWSON UNITED (LIMITED). London. Improvements in electric lamp suspension fittings.

7,127. H. JENSEN, J. JENSEN, and WOODHOUSE AND RAWSON UNITED (LIMITED). London. Improvements in apparatus for indicating the proper working of electrical bells, annunciators, and the like.

7,160. F. WALTER. London. An improved method of producing a hermetical seal for the connecting wires of the filaments of incandescent lamps.

7,167. T. HARDEN and F. E. PEARL. London. Improvements in electric arc lamps.

7,174. G. S. GRIMSTON and E. PERRETT. London. Improvements in electric arc lamps.

7,178. C. J. HALL and R. HAMMOND. London. Improvements in dynamo machines.

April 27, 1891.

7,204. W. KINGSLAND. Chiswick. Improvements in electric alarms.

7,210. G. A. JARVIS. Wellington. The manufacture of improved incandescent lamps.

7,217. W. E. LANGDON. Derby. Improvements in fittings for telegraph poles.

4,271. NEWTON (American Electric Railway Signal Company). Electrical railway signalling. (Price 8d.)

COMPANIES' MEETINGS & REPORTS.

Chelsea Electricity Supply Company (Limited).

The Ordinary Annual General Meeting of the Chelsea Electricity Supply Company (Limited), was held at their Central Station, Draycott-place, Sloane square, London, yesterday. The chair was occupied by J. Irving Courtenay, Esq.

The SECRETARY (Mr. S. J. Cluer) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN then said: Gentlemen, when we met last year the profit and loss account presented to you was for one quarter of the year only, and that the quarter of heaviest demand. There was then shown a small balance to the good, but no Directors' fees had been paid. The amount received for current sold during 1890 was £6,067. 6s. 10d., and the gross profit shown in the accounts before you is £542. 19s. 5d. I may mention that the receipts for the March quarter in this year amounted to £3.275. But you will bear in mind that, although we are now supplying current to over 22,000 lamps, as against 10,000 this time last year, the increasing revenue in respect of these lamps was only even partially felt in the last quarter of the year 1890; and, moreover, the profit on the year's work has been made in spite of most disadvantageous circumstances, which I will now deal with. I allude to the question of heavy consumption of coal mentioned in the report. I regret to say that the consumption during the year has been excessive; but I am glad at the same time to be able to inform you that the unceasing attention to the subject on the part of the management has resulted in the certainty of a reduction of the cost of producing the current as soon as the rearrangement of plant, now in hand, is complete. As the subject is still under discussion, it is not permissible for me at the present moment to say where, in our opinion, the fault lies, but I sincerely hope that an amicable settlement of the difference will be arrived at. There is another point I must touch upon, because it has been the subject of some misrepresentations. Owing to non-delivery of machines, which were ordered early in the year to provide for the winter supply, we were compelled on a few occasions in December, when a heavy drain came upon us through continued foggy weather, to shut off our supply of current for a few hours only in the day time. Some of the plant having shortly after arrived, the constant supply was resumed on December 24th, and maintained throughout the remainder of an exceptionally foggy winter. Now, unfortunate as this undoubtedly was, it still showed the advantages of the storage system; for, instead of stopping the supply suddenly, as might be the case without storage, we were able to give a full day's notice that we should cease supply for a few hours in the daytime, and thus prevented serious inconvenience to our customers. We may congratulate ourselves that we have still the record of not having once stopped supply of current during the hours when light is generally required, and I may also here add that our customers continue to express their entire satisfaction. You will find in the profit and loss account an amount of £253. 6s. 3d. for maintenance of plant. This is made up of small repairs to the different kinds of generating plant, instruments, and tools, and about £50 in wages to men cleaning out the accumulator cells. No expenditure was incurred in 1890 in replacing the E.P.S. storage battery plates, and up to the present day, only one set out of 1,918 sets has had to be replaced, and that at a trifling cost. Now, it must be borne in mind that the replacing of a set of plates is not merely maintenance, as in the case of repairs to a steam engine, but is a complete renewal of the cell, as the other parts for all practical purposes suffer no deterioration. The mains of the Callender Company have also fulfilled our expectations, and have not cost us anything for the repairs of cables. Some of the cables have been underground for over two years, and, from tests taken periodically, it is found that they are still in perfectly good condition. The E.P.S. accumulators are for the first time being used in sub-stations under the direct supervision of our engineer, and so well have they performed their duty that it is difficult, even now, to settle what is a proper amount to set aside for their depreciation. It is intended, however, as stated in the report, to maintain a renewal fund out of profits in order to provide for exceptional outlay in any one year. You will have noticed a printer's error in one of the figures of the balance-sheet, where the figure 9 appears instead of the figure 6. It should be 1,648 shares, and not 1,948 shares. It does not affect the money column. I now come to the present state of the business, and its prospects. You will see by the balance-sheet that the plant has been increased by the amount of £14,660. 10s. 6d. The mains and the generating and storage plant have all had a share in this increase, but the greater part of it is to be found in the extensions of mains, and the erection of a new storage station in Pavilion-road. These additions, together with the plant ordered this year, will enable us to supply sufficient power for about 36,000 8 c.p. lamps installed, which, at the rate of 8s. per lamp installed, would represent a gross income of £16,000 per annum; but this increase would involve the extension of our mains as found to be necessary. Nine shillings per 8 c.p. lamp installed is the figure upon which our experience shows it is prudent to place our estimate of income. I am aware that this is a somewhat lower yield per lamp than that of companies in whose area of supply theatres, hotels, clubs, and shops are numerous, but the shops in Chelsea are now also coming on our list of customers. I think, however, it will be found in practice that the above figure fairly represents the yield per 8 c.p. lamp in domestic lighting. Our district is an excellent one. There is no part of the metropolis where rebuilding is more continually going on, and very few houses indeed in this neighbourhood, as you are aware, are built without being wired for the electric light. We have had added to our area of supply by the Board of Trade a very large portion of the parish of Chelsea, containing about 4,500 houses, including several localities favourable to the development of the business. I do not, however, wish to put before you a too sanguine view of our prospects. I have, therefore, had a careful estimate made of the probable increase during the year in the number of lamps to be supplied, and the result of inquiry points to our reaching a total of 35,000 lamps installed, provided we make the extensions referred to. It is a matter of satisfaction that during a year of financial tightness, and even panic, we have been able to place all the debentures we offered—viz., £20,000—at a moderate cost. The money thus obtained has been carefully dealt with in the most economical manner, and, by means of the new plant already obtained and that on order, we can confidently look forward to a considerable economy in the working during the latter half of the present year. As has been mentioned in the Directors' report, it will be necessary to provide funds for the extension of the mains and for additional plant to meet the increase in the Company's business, and after full consideration the Directors have resolved to recommend an issue of preference shares bearing 6 per cent. interest, and for the present to defer any further issue of debentures. We propose to take power to convert £30,000 of the unissued ordinary share capital into preference shares. This fresh capital will be called up gradually, as required. When this expenditure has been made, the total issued capital of the Company, including debentures, will be about £92,000, or, in other words, the total capital outlay of the Company, including the cost of all stations, cables, and plant, will be, say, £2 12s. per lamp fixed. These figures will compare favourably with those of other Companies, especially when it is remembered that our conduits have a carrying capacity for double the number of lamps I have mentioned.

Digitized by Google

I am prepared to give any further information that may be required, subject to the remarks made at the beginning of my speech. I beg to move the adoption of the Directors' report and statement of accounts.

The DEPUTY-CHAIRMAN (Major-Gen. Webber, C.B.): I have very great pleasure in seconding the motion.

The CHAIRMAN invited discussion, but no one rising to address the meeting, he put the motion, and it was carried unanimously.

The DEPUTY-CHAIRMAN then proposed, and Mr. KING seconded, the re-election of the retiring Directors, Mr. Courtenay and Sir George Prescott, Bart., and the motion was carried unanimously.

The CHAIRMAN, on behalf of himself and Sir George Prescott, thanked the shareholders for re-electing them. He had just received a telegram from Sir George Prescott expressing his great regret at not being able to be present, as he had fully intended to be with them.

On the motion of Mr. SHARP, the retiring auditors, Messrs. Cooper Bros. and Co., were re-elected.

The CHAIRMAN: The next business relates to the issue of fresh shares, in accordance with what I have already said—that we should carry out extensions and add to our plant and so increase our income, and, indeed, fulfil our statutory obligations to give the light to those portions of our area and supply where at the present moment our mains do not extend. I therefore beg to propose the following resolution:—

"*That of the unissued capital of the Company, now amounting to 11,512 shares of £5 each, 6,000 shares of £5 each, and numbered 14,001 to 20,000 inclusive, shall be, and the same hereby are, created and made preference shares, and that such shares shall confer on the holders thereof the right to be paid out of the profits of each year a preferential dividend for such year at the rate of £6 per cent. per annum and no more, and every holder of preference shares shall have one vote for every preference share held by him.*"

Mr. EMILE GARCKE seconded the motion.

Mr. EARNSHAW asked whether any idea could be given to the ordinary shareholders as to when they were likely to receive a dividend.

The CHAIRMAN: I believe the figures we have given in the report answer the question of the honourable proprietor as far as I am able to. The earning capacity of the Company, when these improvements are carried out, and with this fresh capital issued, will represent, I believe, the figures we have mentioned, which are the best estimates that our engineers and others can give us. Our capital is comparatively light for the amount of lamps we shall then have, and though our yield per lamp is not so high as in the case of other companies, still I think it is a fairly safe estimate that our income will amount to £16,000 per annum. It is always very dangerous to prophesy, because it may come back upon one, but I think and believe that when we have carried out these extensions, our fixed charges not being very heavy, and when we are in full swing, the ordinary shareholders will derive some benefit.

Mr. EARNSHAW stated that the gross profit mentioned in the report for the year was £542, but that had been swept away entirely.

The CHAIRMAN: But it is very different when you are dealing with large figures. The whole amount we had to deal with last year was £6.000—a very different amount from an estimated figure of £16,000, because a great many of the fixed charges will remain pretty much the same, and when you deal with a much larger income then will come in the profit. The gross revenue for the first quarter of this year is equal to one-half of the whole amount received last year: and we hope, and it is our belief, that our income will grow in that way, while our expenses should not increase.

A SHAREHOLDER asked for some information with respect to the extension of the business in the last three months in the current year.

The CHAIRMAN: In the latter part of the year our increase was very slight. In fact, we stood still, and we had to stand still. We were not pushing our business in the last portion of the year, because, as I have mentioned, we had at one time to stop the supply, though only for a short time. We were not, however, able to push our business as we should have done had we had the current; and until we get additional plant we dare not push our business. It is far better to keep up our reputation and satisfy our customers than increase the number of our supplies until we are ready to do so, as we should thus have complaints. He then put the motion, which was carried unanimously.

The DEPUTY-CHAIRMAN: I do not think the Chairman omitted the caution which is necessary for anyone in his position to observe, but I think it may fairly and justly go out from this meeting that when we reach the point of earning £16,000, if our expenses and general charges amount at the outside to £9,000, while our obligations towards the debenture holders and preference shareholders amount to £3,000, there is a good £4,000 a year to divide among the ordinary shareholders. I derive, and, as a large shareholder in the Company, I hope that those present will derive the same, comfort from that prospect as I do myself.

On the motion of the Rev. W. J. STOBART, a vote of thanks was passed to the Chairman and Directors.

The CHAIRMAN acknowledged the vote; and subsequently, in reply to a question, stated that it would have been quite as convenient for the Directors to have met the shareholders in the City. Their object, however, in holding the meeting at Chelsea was to enable the shareholders to see the station. The question of meeting in the City was a matter entirely for the shareholders.

The proceedings then terminated.

The following is the Directors' report:—

The accounts are not issued in Board of Trade form, because that course would involve two separate balance-sheets (one for Chelsea and one for Kensington), which would be confusing to the shareholders. This is the subject of correspondence with the Board of Trade, and, when the matter is settled, the accounts will at once be put into such form as that department may require.

The steady progress of the business during the year is very satisfactory. On December 31, 1889, 93 customers, or an equivalent of 8,730 lights of 8-c.p., were being supplied; while on December 31, 1890, there were on the books 252 customers, with lights installed equivalent to nearly 20,000 lamps of 8-c.p. The Company has received for current sold and meter rents in 1890 the sum of £6,067. 6s. 10d., and, after deducting all working expenses, there remains a gross profit of £542. 19s. 5d.

The consumption of fuel in the year 1890 has been excessive; but this is believed not to be due to any defects in the Chelsea system, and measures have been taken which it is hoped will prevent its continuance.

The rate at which the revenue has increased is best exemplified by comparing the two heaviest quarters of the year. In March quarter the receipts for current supplied and meter rents amounted to £1,275. 12s. 3d., and in December quarter to £2,872. 17s. 6d. This affords an indication of the rate of increase of revenue in 1891; and, as the profits should be more than proportionately augmented, the prospects for the current year are favourable.

Under the authority given at the last general meeting, the Directors resolved to issue £20,000 of Six per Cent. Debentures, the whole of which has been subscribed. This has enabled the Directors to repay the loan from its Bankers, and to complete the extensions in hand last year, including new mains and the new storage station in Pavilion-road.

In view of the further extensions necessary to occupy the areas within the Company's districts, the Directors have decided, in lieu of issuing any further debentures at present, to recommend an issue of preference shares, and, with this object, a resolution will be proposed at the general meeting of the Company.

The completion of the plant in accordance with the original plan of the central station in Draycott-place is in progress, and, when the work contemplated for the year has been done, the stations will be capable of earning over £100 during average lighting hours in one day. The experience gained by the Company shows that, under the varying conditions of demand throughout the year in this district, this earning capacity may be estimated to yield a gross revenue of about £16,000 per annum. After paying all outgoings, including the cost of upholding the plant and interest on debentures, the balance should afford satisfactory dividends on the share capital.

The mains, consisting of Callender's Bitumen Cable, of which about 20 miles have been placed underground, are regularly tested, and the results continue to be most satisfactory on all the cables, including many which have been underground for two years. None have had to be renewed on account of defects.

The accumulators are all in good working order. Those at Clabon-mews storage station, which have been longest in use, *i.e.*, for two years, are in excellent condition, and it has not as yet been necessary to replace any of the plates.

The Directors have not dealt with depreciation in these accounts; but care has been taken to keep up all the plant to its original working efficiency. The storage batteries, which constitute a very large proportion of the plant, are under entirely new conditions as regards their working and supervision, and, until experience shows what provision is necessary, a renewals fund will be maintained out of the profits, in order to make provision for exceptional outlay in any one year.

The Directors have to report the retirement of Lord Thurlow from the Board of the Company, and the election of Mr. Emile Garcke (Managing Director of the Brush Electrical Engineering Company, Limited), to fill the vacancy, subject to the confirmation of the shareholders. Mr. J. Irving Courtenay has been elected Chairman of the Company, and Major-General Webber, C.B., Deputy-Chairman while still retaining the post of Managing Director. The retiring Directors are Mr. J. Irving Courtenay and Sir George Prescott, Bart., who, being eligible, offer themselves for re-election. The Auditors, Messrs. Cooper Bros. and Co., also offer themselves for re-election.

Bedford Electric Light Company (Limited).

The annual meeting was held at the office of this Company, St. Paul's-square, on Saturday. Beyond the submission of the balance-sheet, which showed that £150 had been placed to deposit account at the London and County Bank, and that the total expenditure up to date amounted to £33. 14s. 5d. only, the business was purely formal. The retiring Director, Sir Henry Mance, was re-elected, and Mr. James Hull appointed auditor for the current year.

In discussing the position of the Company, the CHAIRMAN remarked that as promised at the previous meeting, they had been extremely careful not to spend a penny unnecessarily, and they would continue to follow this policy, so that if the Company did not eventually undertake the lighting of Bedford, the public would practically receive back their payments in full. In answer to a public invitation from the Corporation to tender for lighting a certain area in the town, the Company had submitted a proposal, which was still under consideration. He thought it would have been better to have commenced in the centre of the town and extend the area gradually. In his opinion, the Corporation had attempted too much, and tried to please everybody, and the question of public lighting was one distinct from private supply. The Corporation could please themselves as to lighting the streets; they might, at least, allow private individuals to use the light if they felt so disposed. With regard to the future, he thought that whether the Corporation did the work themselves or entrusted it to others, the electric light would assuredly be established in Bedford sooner or later. If the Corporation gave the work to other contractors, it would ultimately be necessary to work it by means of a company, and the organisation of the local company already formed would be useful to any parties who might come forward, supposing the overtures already made by the present management were not favourably received.

The West India and Panama Telegraph Company (Limited).

The twenty-eighth ordinary general meeting of the members of this Company was held at Winchester House, Old Broad-street, on Wednesday, under the presidency of C. W. Earle, Esq.

The SECRETARY (Mr. R. T. Brown) having read the notice calling the meeting, the report of the Directors was taken as read.

The CHAIRMAN: Gentlemen, if you adopt the report, this meeting will constitute somewhat of an epoch in the financial history of our Company. It is a marked period, because we shall free ourselves, after this meeting, from the incubus of arrears upon our preference shares—an incubus which has been in existence since 1880. It will also be marked in this respect, that we shall pay for the first time since 1878 a dividend on our ordinary shares—a trifling one, but still a dividend, and the fourth which we shall have paid, in the 21 years of our existence, on these shares. I think I may be allowed to express my appreciation of the self-denial and patience of our shareholders who have borne so long with this unfortunate condition of things; and, perhaps, I may feel justified in taking some little credit to ourselves on this side of the table for having resisted the very numerous financial schemes pressed upon us from time to time, which, if they had been adopted, would have left us to-day in a very much worse position than we are in. Looking at our accounts we see that there is an increase in our gross revenue of £1,210, while the expenses have decreased by £5,175. The decrease in the expenses is almost entirely attributable to our not having had so many cable repairs to execute, and a consequent decrease in the expenditure on cables, and also a saving in expenditure on ships in coal and other matters which have to be incurred when the vessels have constantly to go to sea. The increase of £1,210 has been brought about by several small items. There has been an increase in the traffics of £1,608, but as a set-off against that there is a decrease in the subsidy accounts by our having received only £500 from the Colony of Martinique, against £1,000 in the corresponding period in the previous year. I shall have something further to say about this Martinique question later on. With regard to the traffic returns, it is impossible to conceal from ourselves the rather sad fact—indeed, the very sad fact—that there is no growth or progress in the telegraph returns of the West Indies. We see a very different state of things in the great, temperate-climate Colonies where there are lines of cables. In those Colonies there is progress and growth, and you see an increase in the commercial and industrial enterprise as a consequence. The West Indies are mostly circumscribed in extent, they are islands of limited size, and they are not new countries. It is probably known what can be got out of them, and there does not seem to be any indication of large industrial and commercial growth among them. In such a condition of things it appears to us quite clear that the use of telegraphy in the West Indies must always be restricted, and consequently also comparatively expensive. One would think in such a state of things that we should be free from what is the great bugbear of successful companies—competitive lines—but we are not. First, there is the occasional rumour of what they call the tactical line, some line to serve the purpose of the military department in time of war; and it is supposed that it will be free from all foreign interference. I believe that at the very moment when these tactical lines are wanted there would not be one of them—or, perhaps, a commercial line either—in the region where the military operations were of importance that would not be torn up in a war, and it seems to me most curious that where people have commercial lines they should give large subsidies to carry our tactical lines which would be very destructive to some of the commercial lines, and fail the Government at the very moment when they are wanted. Then we have another class of competitor, which we call the "National Susceptibilities" cable. Under that class I venture to put the French cable which has come into our region. I believe the French have a sort of sore feeling that the communications with their Colonies should all be carried by English enterprise; and they are taking what steps they can to correct that inferiority in their position, as they regard it. I think some of you may have observed lately an account in the papers of a gentleman who is connected with Canada, who is touring in the West Indies, and combining business with pleasure by suggesting to the various communities there that if he is only empowered by subscriptions he will be able to lay lines of cables that will serve all these Colonies—cables, of course, which would never be interrupted, and doing the work at one-fourth the rates which are now being paid. I have no doubt that this gentleman is having a very good time of it in the Colonies, because the liberality and hospitality of West Indians is proverbial, and when a gentleman can preach such a gospel as quarter rates and cables to be always in work there is no doubt that he will be very well received by our West Indian friends; but I think he must be endowed with very great faith in the gullibility of mankind if he thinks that, with the experience which we have gained in the 20 years we have worked the West Indian telegraph business, he can get people to subscribe money on anything like the basis of the advantages he holds forth to the communities. In regard to the Martinique subsidy, the position there has been several times fully explained, not only in the reports, but also by myself in this chair; and when we last met, it was a question whether we should take any legal process against the colony of Martinique for the treatment we had received from it in breaking off, under instructions from the Colonial Office in Paris, their engagement to us for a yearly subsidy. The sum in question was only £2,000, and after taking advice in Paris from a lawyer of eminence there, and fully considering the whole matter, we thought we had better put our pride in our pocket and receive £500—one quarter's subsidy—in settlement. We should have had to bring an action in the colony of Martinique which might have gone against us, and then we should have had to appeal to the Conseil d'Etat in Paris; and considering the expenses we must have incurred I think you will agree that we have acted wisely in accepting the position.

A SHAREHOLDER: May I interpose for a moment to ask if that £500 covers everything, or are there any expenses?

The CHAIRMAN: There are no expenses. Now we come to the laying of a new cable between Demerara and Trinidad. That, I think, has been put before you fully at former meetings and in former reports. I think it was in 1876 that we were able, by a very fortunate arrangement which happened to present itself at that time, to duplicate the greatest part of our system. We did that by an issue of ordinary shares at a figure which, compared with their present price, was very good; but the means at our disposal did not enable us to go so far as to connect the Island of Barbadoes and the colony of British Guiana, and they have been dependent on a single cable since the Company was started. We know from long experience that single cables are not very reliable means of communication, and it has been constantly urged on us by these two colonies, which are important, comparatively, in the way of traffic, that we should duplicate them. Formerly they were in the habit of voting their subsidies yearly. We replied to them, after a great deal of negotiation, "We will lay another cable to each colony if you will give us some fixity of tenure by agreeing to a subsidy for 10 years." The negotiations, especially with Demerara, dragged on for some time, but at last, as our report announces, they have been finally settled by giving us an extension of 10 years of their subsidy, and without alterations in the terms. We have already laid one cable—from St. Vincent to Barbadoes—and now we propose to lay the other to Demerara. When we had decided to lay these cables the question arose how to pay for them, and, after a great deal of consideration, and being convinced that extra lines of cable such as those we propose to lay should be a capital, and not a revenue, charge, we decided then to raise the money on capital account. There are two ways open in raising the money on capital account, one is by making a further issue of Second Preference Shares, and the other is the plan which we finally considered best—to issue debentures for the sum required. With respect to the plan of issuing Second Preference Shares, there would have been this very great disadvantage, that we should have had to pay 6 per cent. for the money; and also it would not have held the balance quite evenly between the liability for this money as among all classes of shareholders. Our First Preference shareholders would have had something more put behind them, which would have been nice for them; but seeing that it would have to be done at a large price, we thought it would not be fair to the Second Preference shareholders or the ordinary shareholders, and we propose, therefore, to issue debentures. With regard to the traffics, I daresay you may have observed a falling off in our receipts this year, but we are now comparing with one of the most successful sugar-growing years, and our traffics do go up and down with the state of the sugar industry in the colonies. We are comparing with, perhaps, one of the most successful years the colonies have had for a long time, and our receipts, though they do show this falling off, are about on a level with what they were in the year before. We have also fortunately been very clear from interruptions this year, and though we are not quite at the end of the half-year (having some seven weeks to run, and one never knows what may happen in seven weeks with cables), still, I think, there is every prospect of the current half-year being fairly satisfactory to the shareholders. I now propose the following resolution:

"*Resolved that the Directors' report and accounts to the 31st December, 1890, submitted to this meeting, be and the same are hereby received and adopted; and that, as recommended by the Board, a payment of 6s. per share on the First Preference shares, being dividend for six months to 31st December, 1890; 34s. 6d. per share on the Second Preference shares (i.e., 28s. 6d. balance of arrears and 6s. dividend for the six months to 31st December); 9d. per share on the Ordinary shares (free of income tax) be and the same is hereby declared.*"

Sir JAMES ANDERSON: I have much pleasure in seconding this resolution, and to save time I ought to express regret at the absence of Mr. Ford, who has seconded the adoption of the report every year since the present Board came into office. I regret his absence, because I think he would have done justice to the report, and would have referred to some points with the enthusiasm which belongs to him; and especially would he have drawn attention to the fact of the dividend which is proposed on the ordinary shares.

Mr. R. J. KING: I should like to make a few remarks, and perhaps on the score of years and seniority of time as a shareholder I might do so. I do most sincerely congratulate the Directors of this Company, to whom I feel deeply indebted for their skilful management of our affairs. They have shown that if you have to have a concern managed it must be managed by gentlemen who understand the business. I think that the Directors have shown that they do understand it. It was said some time ago that we had on our Board the cream of the practical Directors of telegraph Companies. I believe that; and I congratulate the shareholders upon the commencement, as I hope, of better days, the present taste of dividend, which is very pleasant, and which, I hope, is only an instalment of what we shall get in the future. I am able, I think, to tackle figures, and I say without hesitation that I think this is only an instalment of what we may expect in the future. If you look at the accounts you see that there has been a very considerable amount of arrears paid this half-year on the second Preference Shares. This wipes out these arrears, leaving nothing more to pay on that account, and if we took that amount from the credit of the ordinary shareholders, instead of the dividend being 9d. per share it would have been something considerably more; therefore I do hope and believe that we are now beginning to receive some slight advantage from our investment, which, as you have indicated, has been a most unprofitable one.

Sir GEORGE H. CHAMBERS: There are a few observations I should like to make. In the first place, I think I may congratulate our friends on the other side of the table upon their moderation, and I do so for two reasons. One is that moderation is not always to the front, but it will increase the confidence we have that these gentlemen do not lead us with sanguine expectations and then leave us afterwards in the chill of

Digitized by Google

disappointment. Nevertheless, it is well just to glance at the figures, which I have gone over with some care, and I do so more particularly in consequence of your Chairman's observations with respect to the West Indies. I find that our average income in the last five years was £68,000 a year, after paying working expenses. The dividends upon our investment are now £6,000 a year, giving us £74,000. With respect to the Chairman's observations as to the state of affairs in the West Indies, and their telegraphing not having increased, as in other parts of the world, I think I must remind the meeting how seriously these colonies have been injured by the bounty system, and what a dreadful period of depression they have had to go through. Happily, they are recovering from these difficulties. What the Chairman said about the crop of last year is evidence of it. The present crop, through bad weather, is not likely to be so good, but there is no reason why next season's crop should not be as good as that of last year. Though up to the present we have not seen such growth in our traffic as we could wish, I think we have a fair prospect in that direction in the future. I would, however, rather dwell on the figures as they are. Out of our £74,000 a year we have spent on maintenance, which includes not only repairs but additions, £24,700; our Debenture interest is £2,500 a year, and our Preference dividend is £23,500, together £50,700, leaving us £23,300 a year only. That is about £3,000 short of a dividend of 3 per cent. on our ordinary shares. I thought it well to give you these figures. There is another point upon our investments; we have a profit of from £12,000 to £14,000. I should not be at all prepared to recommend that the profit should go to increase the dividend, but rather that it should strengthen the capital. But seeing that the reserve fund stands now nearly at £146,000, and that virtually, looking at its improved value, it is a long way over £150,000, I think the time has come when it should be a matter for consideration whether or not we should apply the dividends on these investments towards the payment of dividends. I rather regret that it was not done in the present instance, because that would have given us a dividend of 1s. 6d. a share, and have still left us with a balance, notwithstanding that the prospect is, as has been stated by the hon. proprietor here, better for a larger dividend even than that in the future. Nevertheless, I so fully concur in the congratulations offered to us by the change in our circumstances, that I not only make that remark, but I do not propose any alteration in what the Directors suggest.

The CHAIRMAN: Gentlemen, I beg to thank you for the flattering remarks which have been addressed to us by Mr. King in the first instance and afterwards by my friend Sir George Chambers. It is true that we do not see Mr. King here sufficiently often, and this is the first time for a great many years that we have had the pleasure of seeing him at our meetings. I am very thankful to him for the kind way he expressed himself about us. As to Sir George Chambers' views, being so encouraging they are of very great value, because no man knows more about the West Indies, their trade and position than Sir George Chambers; and when he speaks so hopefully and in such an encouraging way of our field of enterprise, I think that we all feel a little comfort. The suggestion he has made about the reserve fund causes me some little difficulty, because our reserve fund is calculated upon three factors—the life of a cable, the price of a cable, and the amount of interest we get upon our investments. If we were to stop interest accruing to the reserve fund, then that fund would remain where it is, but the depreciation of our cables is going on every year, and we have taken a very long life for a cable—30 years—as the basis. It is, however, incumbent on us to set aside in one way or another, either in new cable or renewals, or in interest on the reserve fund, such a sum as will keep level with the depreciation that is going on. It is for that reason that in the present half-year we find that our calculated reserve fund is what it ought to be up to the date at which the accounts close—the 31st of December last year; and therefore we are not under any necessity of adding to it. It is added to itself practically by the new cable put in during the year, which goes into the account, and also by some £2,800, the interest upon the half-year. These accumulations have gone to the reserve fund, and have obviated the necessity of making any direct contribution to it. I think that it is essential to keep the reserve fund up to the proper amount to represent the depreciation that is going on year by year in our cable. The cables have been down a good long time now—20 years—and though it may seem a large sum that we have at the credit of the reserve fund, if you think that we have over 4,000 miles of cable, and what it would cost to have any extensive renewal of the lines, I believe you will see that a reserve fund of £150,000 is not an extravagant figure.

Mr. TREBLE: May I ask if the increase of the debentures will involve an increase of £2,500 a-year in the charges?

The CHAIRMAN: It depends on what we can issue them at. It will involve an increase, of course. He then put the motion, and it was carried unanimously. Continuing, he said: I now propose the resolution with respect to the debentures as follows:—

"*Resolved:—1. That the Board be and are hereby authorised to borrow and raise from time to time such moneys, not exceeding in the whole* £100,000, *as they may think necessary for any of the purposes of the Company, including the payment off and extinguishment of the existing* £50,000 *Debenture debt falling due on December 31, 1891.*

"*2. That the Board be and are hereby authorised to raise the said* £100,000, *or any part thereof, at such times, at such rate of interest, and on such security, terms, and conditions in all respects as they may think proper, and also from time to time to execute and issue Debentures and other securities or obligations of the Company in respect of such moneys.*"

I think the report clearly states what are the limits and purpose of this demand upon you with respect to the increased power asked for in regard to an increase in the debenture debt. It is quite clear that £100,000 is the limit of the power we ask you for, and £50,000 of that will replace the debentures now extant, and the other £50,000 will go to pay for the new cables which will add so much strength and permanence to your system.

Mr. W. S. ANDREWS: I beg to second the resolution.

Mr. COPP: Before you put that, may I ask a question? I perceive that in consideration of laying these cables you get a subsidy of £4,500 a year from one of the Colonies. Is that in excess of the previous sum, or the same?

The CHAIRMAN: The same. We spend this money without any further subsidy or any other advantage except the extended time.

Mr. COPP: It will be permanently an extra charge?

The CHAIRMAN: Yes; but there will be an economy in connection with this expenditure. When these cables are interrupted, and being single cables that happens pretty often, the Colonies stop the subsidy, ships have to be put on to carry the messages, and the repairs have to be done very quickly. We have to take the ships from wherever they are, and to press on with the work of repairs as quickly as possible. All this means considerable expense, and this outlay is, therefore, not all pure outgoing.

Mr. COPP: There is another point I should like to refer to. With respect to the reserve fund, it has occurred to me that it might be a profitable investment to invest the fund in our own debentures. We have a lot of investments which can be sold to pay 3½ per cent. Is there any reason why the money should be kept in these securities instead of putting it in our debentures, and so saving, perhaps, £1,000 a year? It strikesme that there might be a considerable saving by that means.

The CHAIRMAN: No doubt, from a mere financial point of view, that sounds, and is, very good finance; but one of the great objects of a reserve fund is to have something that you can realise in a moment of difficulty. Suppose, for instance, a serious break occurred in the two long cables that go from Jamaica to Porto Rico, and it was found that the repair would take a long time to effect and cost a great deal of money, we should then have to go into the market, and we could not do so with the same advantage if our reserve fund was invested in our own debentures as we could go now.

Mr. COPP: I do not propose that you should use all the reserve fund for investment in our debentures—say, £50,000.

The CHAIRMAN: Well, £100,000 would not go a long way in repairing a cable like this. I think we had better keep our reserve fund in convertible securities.

Mr. KING: I hope you will not touch the reserve fund by one farthing, for by doing so you would diminish our security. You want something that you can realise at a moment's notice if you require the money. If you were to invest our reserve in our own bonds it is a mere levelling down into the whole mass, and is lost as far as your power goes to use it.

The CHAIRMAN put the motion, and it was carried unanimously.

Mr. C. W. Earle and Mr. W. Ford were then re-elected as Directors, and Mr. J. G. Griffiths as auditor, and a unanimous vote of thanks to the Chairman brought the meeting to a close.

The Western and Brazilian Telegraph Company (Limited).

The twenty first ordinary general meeting of this Company was held on May 8th, 1891, at Winchester House, Old Broad-street, London, under the presidency of W. S. Andrews, Esq.

The SECRETARY (Mr. R. M. Cunningham) read the notice convening the meeting, and afterwards the minutes of the twentieth ordinary meeting, which were approved by the present meeting, and signed as correct by the Chairman. The report and accounts were taken as read.

The CHAIRMAN: It is again my pleasing duty to report to you that the receipts are once more of a satisfactory character. They have amounted for the past half-year, to the 31st of December last, to £108,817. 10s. 5d., as compared with, in the corresponding period of the previous year, £86,403. 0s. 7d., showing an increase of £22,414. 9s. 10d. Well, of course, that is a very gratifying state of things. We cannot particularly ascribe it to any one cause, but as far as we can trace cause and effect, no doubt, the large speculation that there has been, the excellent crops that have been talked about, the excitement in the countries concerned, and the political difficulties of the time, have all combined to assist in producing the result which we have reached. As regards the expenses, they amounted for the same period to £37,200. 2s. 4d., and they compare with £40,391. 11s. 9d., so that there is a reduction in the expenses of £3,191. 9s. 5d. Now, these two antagonistic things will no doubt be satisfactory to the shareholders, because they take place in those respective departments of the accounts which by this comparison end in giving the shareholders more money. In analysing Abstract A, which is that relating to the expenses at the stations abroad, where the money is earned, we find that there are seven items of increase and six items of decrease, and that there is one item that has not appeared before in the accounts—namely, that for establishing duplex apparatus at the stations. Omitting the duplex—which, of course, is not an annual charge, and does not come properly into this expenditure, and will not occur in this particular case again, the expenses show an increase of £1,298. 19s. 2d. Well, of that total £1,198. 18s. 8d. are the expenses of working these stations. Tho e represent the main cost indeed of earning the revenue, and are occasioned by mechanical increases under old agreements; promotions in the junior staff, which is always getting older, like most of us, and becoming senior staff instead of junior staff; and a good deal more work. The remaining increases and decreases under that head practically balance one another. They are all small, and it is not necessary to labour this, because it will not give you any information that is of any use. I will now take Abstract C, because that rather belongs to the same question of expenses, that is, the expenses in London. The expenses under this abstract for the half-year were £2,961. 12s. 2d. compared with £2,710. 8s. 5d., so there is a small increase there of

Digitized by Google

£251. 3s. 9d. That is spread over five items. There has been a good deal more work to do, and a bonus was given at Christmas to some of the junior clerks. Now, gentlemen, you see there is that increased expenditure in the commercial staff, the whole of which comes to a sum of about £1,400, and you will be glad to know, probably, what additional work has been done for this not very considerable sum of money. The additional work done, you will perhaps be rather surprised to hear, amounted to 31 per cent., so that that is an outcome which, I think, you must all agree is exceedingly satisfactory. Next I will deal with Abstract B. It is under this abstract that the real saving of the year has been made, and it is owing to the fact that in the half-year under review there was no ship under charter. You will remember that at the corresponding period in 1889 we had a ship under charter, and that consequently our expenses under the head of shipping were considerably increased. There is, of course, an increase in our own shipping expenses of £3,508. 16s. 6d., because our ships had to do all the work. The "Norseman" was very busily employed; the "Viking" was not so busily employed, and there was a small saving on the "Viking." The great feature, however, remains that the chartered ships item, amounting to £8,531. 1s. 3d., is entirely removed from the account, and the consequence of that is a reduction under shipping of £5,434. 8s. 10d. It is satisfactory, too, that this reduction would have been greater had the ships been fortunate enough in the past half-year, as they were in the corresponding period of the previous year, to get some charters, because we had two charters in that half-year, and we received under that head £1,762, which went against the expenses. We have not been so fortunate this half-year, but still we have done well. The cable used cost us £234 less; but the depreciation in ships has been £229 more. Well, the net result of all this is not bad. The revenue we have earned is £22,414 more, and the money that has been spent to earn it £3,191 less. The gross receipts for the half-year were £108,817. 10s. 5d., and the gross expenses were £37,200. 2s. 4d., so that there is left £71,617. 8s. 1d. Adding the amount brought over from the preceding half year, £5,751. 7s., and the dividend on the Platino shares, £9,233. 10s., you get at the gross amount which you have to deal with—£86,602. 5s. 1d. Then you calculate interest on the debentures, £13,164; the amount placed to debenture redemption fund, £5,936, and the similar sum put to the reserve of £20,000. These three items amount to £39,100, and there is a sum left of £47,502. 5s. 1d. We recommend you to declare a dividend of 9s. a share, making up 5 per cent. for the year. That will take £41,431. 19s., and it will leave £6,070. 6s. 1d. to carry forward to the current year. That, gentlemen, concludes our dealing with the figures. You will remember that at our last meeting we reported that, after very considerable delay and very great trouble, we had succeeded in obtaining from the Government their consent to our laying certain loop cables for the purpose of strengthening and improving the system. One of these loops has been already laid between Monte Video and Chili, and it appears in the Company's accounts. The next sections are, I believe, made, and will go out very shortly. They extend from Pernambuco to Bahia, from Bahia to Rio, and from Rio to Santos; and they cover the chief portion of that part of the system south of Pernambuco where our revenues are mainly earned. We believe that these loops will be sent out and be laid by about June, and when they are laid, of course, your property over the district which they cover will be more secure than it has ever been before, and, of course, it is likely to remain, as far as one can see, uninterrupted. Well, there was one rather unpleasant feature in connection with this business—that is, that while all these negotiations were going on, the price of cables was rising. Gutta percha was becoming dearer, companies were having to pay more for labour, and so on. However, the course adopted by the Company was, no doubt, one you will approve—that of proceeding by tender, by which means the best prices that could be got were got, and the lowest price was accepted—the tender of the India Rubber, Gutta Percha, and Telegraph Works Company—and we know that from them we shall get a thoroughly trustworthy line of cable. The ordering of cables may be pleasant enough, but there is another consequence that follows, they have to be paid for; and the question with us was: How are we going to pay for these cables? We have no capital, as you are aware, and there are no means of issuing capital. Our debenture arrangements are such that we could not issue debentures to the public, and, after citing no end of means by which it could be done it really seems as if there were only one way of doing it—that is, to pay for these cables—for the present, at all events—out of the reserve fund. Owing to the increase in price, there is some £185,000 to be provided. This, of course, is a pretty heavy draft on the reserve fund, but we propose to strengthen that fund by issuing the £50,000 of debentures which we still have power to issue, but which we shall not offer to the public. We propose to issue them at 4 per cent. only. We have our reasons for that. We should place this issue in the reserve as a payment back by capital to revenue for money originally taken from revenue, and we should issue them upon terms which would enable us to recall them, so that we should not interfere with any big measure we may be enabled ultimately to carry with respect to the debentures generally. Well, we have to sell investments to produce the money. We have made our calculations, and we find that on the sale of the stocks which we have selected for the purpose we shall secure a profit of £11,000. That is a satisfactory fact, and of course it goes in reduction of price really, because it is a something that has been created out of nothing—an unearned increment. Counting £50,000 of debentures and this profit the reserve will still remain, I am pleased to say, at a very respectable figure, namely, just upon £100,000, actually about £99,000; and the additional charge for these new lines will be very small. Altogether, what with the arrangements we made some years ago to devote £26,000 to paying off discount on previous issues of debentures, and what with the liberal policy, I will call it, of the shareholders—at the same time, I think the wise and discreet policy of the shareholders—we are enabled to carry out this great work—for it is a great work—for the improvement of your property entirely out of the savings of the concern. Your reserve is so strong that you are able to draw upon it for this very considerable addition to your system. It is a satisfactory circumstance, that the bed of the ocean where these cables are going to be laid is one suited to our purpose. It is too deep for anchorage, and it has about as good a bottom as we could possibly have to put our property on. This measure ought, of course, to give increased security to our trade. It will diminish interruptions, it will make us stronger, and certainly preserve, if not improve, our revenue, because, although, I am pleased to say, the service is efficient now, and our officers deserve credit for it, yet I think we may improve it notwithstanding. We are none of us perfect, and if we have additional means of making our service even more efficient than it is, no doubt our officers will know how to make use of them. The question has been very often in the minds of the proprietors: What are we to do with the debentures? This has been a sort of "old man of the sea." It has never been off our shoulders. If there has been one, I should think there have been half-a-dozen schemes for dealing with this question. We have taken all sorts of advice, consulted all sorts of people, and we began almost to despair of devising something which would conciliate all interests, especially the legal interest. However, in the end we are told by great legal luminaries that we have surmounted the difficulty, and that we have got a scheme which will avoid all the legal pitfalls, which is as simple a scheme as can be expected under the circumstances—that is the highest praise I can give it—and that consequently we may congratulate ourselves upon having a something now which can be carried out from the legal point of view. But, of course, there is something over and above the legal point of view. We have no compulsory powers with the debenture holders, and we must, therefore, convince them that their position is in no way prejudiced, but rather improved, by this scheme. We must conciliate them as permanent investors. We have only within the last 30 hours got the final legal opinion, and, therefore, we have not been able, as we should otherwise have done, to consult some of the larger debenture holders. We shall, however, consult them, and we shall see whether, as a commercial as well as a legal business, we can make our scheme go. If we receive encouragement from our debenture-holders we shall try it. We did not think it worth while to come before you with any proposal, because the thing, though ripe in a sense, is not quite ripe enough. When we have received opinions which we can rely upon it may be that we shall call you together to consider this matter, which is very important, largely concerning your future interest, and one which will, I think, if favourably resolved, considerably improve the *status* of your property. When we last met there was another thing hanging heavily on our minds—namely, the question of the competition of the various lines projected at that time. There was an Argentine line, but that seems to have dropped. There was another line to the North—to the United States, which also seemed to have dropped, but this has been revived. The Paris Telephone Company appears to have so much money since its purchase by the State that it does not quite know what to do with it. So it has taken up this line to the United States of America. A section has been laid from Martinique down to Parmarhibo, in French Guiana, and the expedition is going out, or has gone—(A voice: Gone)—to extend from Parmarhibo to Vizeu, in Brazil. Then I believe the expedition goes North and lays a length of cable from Guadeloupe to Puerto Plata, and the idea is that the scheme should ultimately be extended to America. We do not know whether it will be or not. We have always felt that under our concessions in Brazil we had certain rights in the more commercial provinces which would safeguard us to a great extent from the effects of competition; but however that may be—whether we have that protection or not—I am sure that all of us will be of opinion that "threatened men live long." We have been threatened for many years, and are still alive, and pretty prosperous; and I am not quite so sure, looking at the elasticity of the traffic, looking at the fact that the Western and Brazilian and the Brazilian Submarine Companies have the direct route—you see from this map that it is almost a straight line from Europe and the United Kingdom to these places, whereas the other people go all round the western world to get there—I think, looking at that fact, and that the Brazilian Submarine Company has entirely duplicated its system, and that our system will very shortly be duplicated over all the busy parts—I say that, looking at all these matters, we may not have to fear these lines so very much. We may be enabled—and I hope we shall—to hold our own. We are experienced in the work; our men are all up to their business. The work is well done and quickly done, and I doubt whether these other lines will find that it is quite so easy as they may think at the present time to make considerable deductions out of our revenues and put them into their own pockets. I think we shall have something to say to it, and I think, at all events, that we shall do our very best, as I hope we have always done, to keep your traffic together, and to continue, as far as lies in our power, the present current of your prosperity. I daresay, gentlemen, you have noticed another thing, namely, what I should call the abnormal traffics of this current period. The traffics, you know, have been immense, and I do not want you to go away and think that in what I have said I have been referring to the preservation of these traffics. I am not. I am only speaking of the normal traffic. These present large sums that you see figuring every week in the papers are caused by the fact that Chili is in a state of difficulty. The telegraphs are all stopped, including the line at Valparaiso, which competes with our system. These lines cannot take any traffic from Buenos Ayres and Monte Video, and send it round by Chili, and therefore we get practically all this traffic. You must therefore be prepared, without the slightest feeling of discouragement, for a reduction of traffic at the end of this war business in Chili, and you will get to your normal revenues; and I do hope, as they have been fairly satisfactory for a long time past, to keep them. We shall do our best. When these East Coast lines get through we shall lose a large part of the abnormal business, but still some of it will cling. There is a sort of inclination on the part of people to stay when there has been a long interruption like this. I do not know that I have anything more to say, and therefore I will conclude by moving—

"*That the report and accounts to the 31st December, 1890, be hereby approved and adopted, and that a dividend of 9s. per share, free of income-tax, making, with the interim dividend paid in November last, 5 per cent. for the year 1890, be, and is hereby declared, payable on the 13th inst.*"

Mr. H. WEAVER: I beg to second that.

The CHAIRMAN: Before putting this resolution to the meeting, I shall be very happy to reply to any question that any shareholder may like to ask.

Mr. PETO congratulated the Directors on the successful report which they had issued, it being a most satisfactory feature that, while there had been an increase in the receipts, the expenditure showed a diminution. He had recommended many to invest in the Company, and he was pleased to say that in all cases his friends had doubled their capital.

Mr. CLARK asked whether the difference between the amount of the investment and the sum under the head of reserve fund was in cash in hand; and whether the "Norseman" was engaged in laying the new lines. Was it intended to work with one ship?

Mr. JACKSON thought all the shareholders must feel satisfied with the report and the Chairman's statement; and he thought the Chairman had acted rightly in pointing out distinctly that the present traffic was exceptional, due to the disturbances in Chili. It appeared to him that their position was most sound and satisfactory, especially as there was to be no call for fresh capital in this most stringent time, when such an absence of confidence existed.

Mr. ENNIS also said he thought the report and accounts might be issued with less delay than at present.

Mr. COPP inquired whether the ordinary shareholders would have an opportunity of tendering for the £50,000 of debentures which were to be issued.

The CHAIRMAN: It is not proposed to issue the £50,000 of debentures to the public. The money will be put into the reserve fund really, for the purpose of strengthening it, in view of the considerable sum which we are taking out of it, and we are not issuing it to the public because of the more extensive arrangements with respect to the debentures to which I have referred.

Mr. HUBBARD: In the last balance-sheet I see the words "reserve fund" instead of "renewal fund." Is that a clerical error or intentional?

The CHAIRMAN: It is intentional. Reserve, as a fact, is not confined to the one thing which the word "renewals" implies. With respect to the reserve fund, an honourable proprietor drew attention to the fact that there is a certain difference between the amount under the head of investments and the total amount under reserve fund. The difference between the two exists in cable and ships. A portion of the reserve funds, in other words, had to be invested in spare cable and ships, because, as I have previously mentioned, we have been deficient in capital. Another question was asked as to whether the Company, in view of the increased safety of its system, would work the system with one ship. That is a question which at present, with every deference to the honorable proprietor, I am not in a position to answer. The next very proper question put by Mr. Jackson is as to this four months' delay, as he says, in getting the accounts over. It seems a very simple thing to get accounts over when you come to calculate the number of days taken and that sort of thing, but we have 13 stations in all parts of Uruguay. These stations are situated—some of them—in rather awkward places, and, as a fact, it takes a very long time to get the information into the office, to get it checked at the office, and to have the requisite control over the expenditure, and so on, locally. All these things have to be returned to and fro; otherwise you would get everything accepted, and your expenses would be considerably increased. A check, however, must be kept, and these things have to go backwards and forwards. Then they are sent over here to work out. We have also to exchange accounts with our partners. On the whole, I can assure you that we present these accounts as soon as we possibly can. By-the-bye, I did not explain what has just been pointed out to me by the Secretary—that we cannot hold our meeting until the Platino Company hold theirs, because we must get their dividend paid to us; and they must hold their meeting, under their Articles of Association, in May. I do not think there are any further questions remaining to be answered.

Mr. CLARK: I asked whether the "Norseman" has been laying the new cables?

The CHAIRMAN: Oh, no, that is a large expedition. You want a ship of 5,000 tons for the purpose.

Mr. CLARK: But what is the reason for the expenses being so heavy in connection with the ships?

The CHAIRMAN: Ships must and do cost a large amount per annum, breaks or no breaks, because they must be on the spot. You find that if they are very much in port the expenses are very much less, because of the coal which is used when they are much employed in steaming. He then put the motion in the usual way, and, having declared it unanimously carried, vacated the chair pending his re-election.

Mr. W. S. Andrews and Lord Richard H. Browne were then re-elected as Directors, and Mr. John Weise and Mr. J. G. Griffiths as auditors, and, after a cordial vote of thanks to the Chairman, the meeting separated.

NEW COMPANIES REGISTERED.

BOY MESSENGERS AND ELECTRIC CALL COMPANY (LIMITED).—Registered by P. B. Ryan, 11, The Members' Mansions, Victoria-street, with a capital of £200,000 in £1 shares. Object: to acquire the business of the Boy Messengers, Limited, and to work the messenger and electric call system in London and elsewhere, within a radius of five miles from the General Post Office. There shall not be less than three nor more than twelve Directors. The first are Captain W. H. Davies, Lord Frederick Hamilton, Sir Frederick Milner, Bart., M.P., the Hon. P. B. Lyon, and R. King. Qualification, £100. Remuneration, £2,500, divisible.

CITY OF BATH ELECTRIC LIGHTING AND ENGINEERING COMPANY (LIMITED).—Registered by Kingsford, Dorman, and Co., 23, Essex-street, Strand, W.C., with a capital of £60,000, in 5,500 ordinary £10 shares and 50 £10 founders' shares. Object: to adopt and carry into effect an agreement made May 2 between Henry George Massingham of the one part, and the City of Bath Electric Lighting and Engineering Company (Limited), of the other part, and to carry on generally the business of an electric light and power company. The first subscribers are:—

	Shares.
T. Vaughton, 7, Cavendish-place, Bath	50
J. G. Jervois, 16, Lansdowne-place East, Bath	50
A. Pitman, 12, Royal-crescent, Bath	50
E. B. Titley, 15, Orange-grove, Bath	50
H. N. Garrett, 101, Sydney-place, Bath	50
E. Pitman, 12, Royal-crescent, Bath	50
W. Jeffery, 2, Northumberland-buildings, Bath	10

There shall be not less than five Directors. The first are Lieut.-Colonel Theo. Vaughton, H. N. Garrett, A. Pitman, Major-General J. G. Jervois, and H. G. Massingham, all of Bath. Qualification: 50 ordinary or five founders' shares. After payment of a 6 per cent. dividend upon the ordinary and founders' shares, the remuneration of the Directors shall be £500, divisible; failing the payment of such dividend, the sum of £250, divisible. Such sum of £500 shall be increased as soon as the actual paid-up capital, exclusive of founders' shares, exceeds £50,000, by a further sum of £50 for every £10,000 of additional share capital actually paid up.

EUROPEAN SIMS-EDISON ELECTRICAL TORPEDO COMPANY (LIMITED).—Registered by J. Andrew, 15, Marriott-road, N., with a capital of £201,000, in 10,000 ordinary £20 shares, and 1,000 £1 Founders' shares. Object: To acquire certain patents relating to torpedoes, and to carry on the business of an electrical company in all its branches, in Great Britain and any part of the world. The first subscribers are:—

	Shares.
E. H. Edwards, 30, Pellerin-road, Stoke Newington, N.	1
E. Sorrell, Oak Cottage, Fowler-road, Forest Gate, E.	1
J. Andrew, 15, Marriot-road, Tollington-park, N.	1
A. M. G. Carter, 40, Denning-road, Hampstead, N.W.	1
R. H. Ibotson, 37, Chatham-road, Wandsworth-common, S.W.	1
W. Brown, 121, Hungerford-road, N.	1
S. Woodham, 82, Evelina-road, S.E.	1

There shall not be less than three nor more than 12 Directors; the first are the signatories to the memorandum of association. Qualification, being a shareholder. Remuneration to be determined in general meeting.

ROPER'S ELECTRICAL ENGINEERING COMPANY (LIMITED).—Registered by J. M. Urquhart, 10, Denbigh-street, Warwick-square, S.W., with a capital of £15,000 in £1 shares. Object: to acquire the business of Roper's Electrical Engineering Company (late John and William Roper), electrical engineers, Trafalgar Works, Trafalgar-street, Bradford, Yorkshire, and to carry on and extend the same. Registered without articles of association.

CITY NOTES, &c.

BOY MESSENGERS AND ELECTRIC CALL COMPANY (LIMITED).—The prospectus of this Company, formed for the purpose of acquiring and extending the business of the Boy Messengers (Limited), was issued last week. The total capital of the Company is £200,000 in £1 shares, and the first issue was for 80,000 shares, the subscription list opening on Friday and closing on Monday. The prospectus states that after protracted negotiations the Company have obtained from the Postmaster-General the promise of a licence to work the electric call system. Amongst the Directors is Captain W. H. Davies, the managing director of the Exchange Telegraph Company (Limited), and the secretary is Mr. J. L. Burn, with offices at Billiter House, Billiter-street, E.C.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the past week amounted to £4,981.

CITY AND SOUTH LONDON RAILWAY COMPANY.—The traffic receipts of this Company for the past week amounted to £695.

GREENWOOD AND BATLEY (LIMITED).—The Stock Exchange Committee have ordered the undermentioned securities of this Company to be quoted in the official list:—Vendors' preference shares, Nos. 1 to 2,666; further issue of 2,600 ordinary shares, Nos. 14,001 to 76,800; further issue of 1,600 preference shares, Nos. 8,001 to 9,600.

RUSTON, PROCTOR AND CO. (LIMITED).—Notice is given that the transfer books of this Company will be closed from May 8th to May 26th.

ST. JAMES'S AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED).—Application has been made to the Stock Exchange Committee to appoint a special settling day in, and to grant a quotation to, this Company's ordinary and preference shares.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended May 8, 1891, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,964.

THE NON-CONDUCTOR OF ELECTRICITY.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.

MOSSES & MITCHELL, 70, Chiswell-st., London, E.C.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 679.—Vol. XXVII. FRIDAY, MAY 22, 1891. Price Fourpence.

NOTES.

The reply of Dr. Fleming to the brief discussion on his exhaustive Paper dealing with a phenomenon which, for lack of a briefer name, has been called the Ferranti effect, will doubtless be the last word in a controversy which must have become somewhat wearisome to many of our readers. Mistaken accounts have been put forward both as to the tests made and the results obtained, and much unnecessary trouble has been expended on a matter the purely scientific interest of which is not supremely great and which is as yet of little practical importance. It was stated, during the discussion, that Dr. Fleming's Paper contained the first clear and true account of what was actually observed. Without going into the question of clearness, we venture to maintain that our leading article of 10th December, 1890, contained the first accurate statement, and described the way in which the rise of pressure was originally discovered by the engineers engaged in laying the mains.

We would remind our readers that Prof. Ewing will discourse at the Royal Institution, this evening, upon his very simple and beautiful theory of induced magnetism, and there is every reason to expect that this Institution will provide means for carrying out the experiments on a scale more in keeping with their importance than was found possible at the meeting of the British Association at Leeds, when they were first shown in public to an audience of some 20 persons or so, crowding round an apparatus inefficiently worked with a few cells.

A very remarkable confirmation of Prof. Ewing's theory comes to hand on the eve of the Royal Institution discourse, in the form of an article by Mr. Arthur Hoopes, in the *Electrical World* of New York, of May 16th. A mass of magnets, consisting of three layers of Ewing's needles, formed, as it were, the core of a magnetising coil. The magnetic moment of this coil was measured by a magnetometer, the usual precautions being taken to eliminate the influence of the magnetising current. The magnets were stirred up, and allowed to come to rest, a magnetising current was applied, and the magnetometer deflections carried through an ordinary **B-H** cycle. The result is a set of curves, jagged and discontinuous, it is true, but exhibiting all the well-known characteristics of the hysteresis curve. The small initial susceptibility is shown admirably, and even small loops superimposed on the main cycle are clearly represented, although only 68 needles were used.

We regret that it is impossible to convey to our readers by means of illustrations the extremely pretty experiment which embodies Prof. Ewing's theory. The first gradual inclination of the magnets, increasing to a distinct swerve in one direction; then the point at which instability begins, and the tottering of first one and then another needle, and the quick swing into a new position; then the unanimous facing about of the entire company; and, lastly, the gradual and decreasing effect of the strongest possible magnetising current upon the needles under its command, must be seen to be appreciated.

Workshop experiments, carried out by engineers, possess an advantage over laboratory researches of the student of pure science in that such experiments are generally carried out under the conditions of practical work, and their results are intended to apply directly to workshop practice; and such, to a large extent, has been the case in the interesting investigations which have formed the subject of the recent Paper by Mr. Vignoles. With a praiseworthy disinclination to acknowledge the applicability of the work of Hopkinson and Ewing to the design of transformers, the author, together with Mr. Evershed, started *de novo*, and, assuming nothing whatever, have made solid contribution to our knowledge of magnetism. Under these circumstances the fact that they have somewhat misused the term "induction," and have coined, for private use and with but little gracefulness, the word "thom," may, perhaps, be excused, for they do not set up as teachers, and ask no one to follow them.

It appears from the introduction to the Paper that the experimenters had applied themselves "to the consideration of the action of iron in transformers," but Mr. Vignoles informs us, in a letter which will be found in another column, that, iron alone being under consideration, leakage must not be taken into account, and on this ground he takes exception to the criticism which we made in our last issue. It is true that leakage has no influence on the form of the **B H** curve, but when **H** is calculated from the magnetising current in a particular coil, and **B** from the induction produced in a surrounding search coil, the curve so obtained may be affected by it. Our correspondent virtually admits our contention by stating the importance of the leakage question in transformers.

The action brought by the National Telephone Company against Mr. Andrew Erskine Muirhead, of Glasgow, a report

Digitized by Google

of which will be found in another column, raised the delicate question of the meaning of "experimental use." Mr. MUIRHEAD, convinced of the superiority of the Ader and Berthon transmitters, proceeded last summer to advertise and circularise his convictions, with the natural result that the National Company brought him into Court. It was not denied that the transmitters in question were infringements of the patents owned by the National Company; but it was urged that the instruments were merely sent out for inspection and experimental use, no profit having been made by Mr. MUIRHEAD. The evidence on this point was somewhat conflicting. In the end, however, the National Company agreed to accept £50 damages, plus an injunction and the delivery up of the infringing instruments, the judge, to his manifest relief, being saved the necessity of defining where commercial use begins and experimental use ends.

OUR contemporary, the *Engineer*, in a short article on the reduction of the telegraphing rates to Australia under guarantee by the Australian Governments, makes the remark that "the costly cables which lie under the waves have only a partial use as yet." It is often assumed by those who have not had practical experience of submarine telegraphy that the whole 24 hours are available for transmitting messages, and this is sometimes in prospectuses made the basis for revenue estimates; but, as a matter of fact, the telegraphic working day between England and America, for instance, is only about 15 hours. Between Great Britain and Egypt practically the whole of the traffic must be carried between the hours of 9 and 5. In the case, however, of telegraphic correspondence between countries the difference of time between which is greater, the traffic is more evenly spread over the 24 hours; but even in this case the telegraphic working day is only about 18 hours. Australian time being 10 hours and Indian five in advance of English time, messages are as a rule sent one day and the replies received the next. The transmitting capacity of long cables is, however, strictly limited, and the existing sections to Australia being already duplexed, any very considerable increase in the number of messages would necessitate more cables. In fact, in view of the expected increase of Australian traffic, additional cables were laid from Suez to Bombay and from Madras to Penang at a cost of nearly one million sterling.

AN electro-magnet for the transport of iron castings has been in use for some time at Pittsburg, and the exhibition at Frankfort of one which is capable of lifting a ton, suggests the consideration of the question whether this is an economical or proper use of electric current. Of course, anyone who is connected to a supply company can heat baths and toast bread by electricity, but it would be an expensive amusement. A crane hook should have a factor of safety of 6. Should the magnetising current have a similar factor? The crane-hook will either support the load or it will snap; very rarely the first yielding may be detected in time. But an electro-magnet always has a certain (or uncertain) amount of "sticktion," and unless the current is interrupted, or the coils are short-circuited, it cannot fail to act. But if the casting be properly slung, the crane-hook cannot, on account of its shape, slip its load. Can the same be said of a magnet? The uncertainty of the good condition of the slings is eliminated, but there would seem to be some difficulty in both roughing a magnet so as to prevent lateral slipping, and at the same time providing sufficient surface. The economy of the matter is also rather obscure. A factor of safety of 6 in a crane-hook means that so much capital is invested in dead material, and is lying there, whether the hook be used or no; but as the current is only used while the lifting magnet is actually employed, the cost of the additional quantity demanded by the factor of safety is inconsiderable, always supposing there is a plentiful supply to draw upon. But the magnet itself must be of sufficiently large dimensions to allow the use of the large current; in fact, the magnet itself must be designed with an ample factor of safety. Electrical engineers are not so familiar with factors of safety as their mechanical *confrères*, and we doubt whether the application of electricity for the purpose of lifting and carrying iron castings will commend itself to the latter.

THE Electrical Exhibition at Frankfort promises to be a great success, and will afford some interesting information as to the popularity of various systems on the Continent. We publish this week the second of a series of articles which will be continued from time to time, and will describe some of the more important exhibits. The much talked-of transmission of 300 H.P. over 110 miles at a pressure of 25,000 volts will unfortunately be delayed until the middle of August.

The Electric Lighting of Barnsley.—We learn by telegraph, at the moment of going to press, that, at a meeting of the Barnsley Corporation, held yesterday, it was resolved to adopt the Lighting Committee's recommendations.

Royal Society.—The ladies' soirée of the Royal Society will take place on Wednesday, June 17th.

Society of Arts.—The conversazione of the Society of Arts will be held at the South Kensington Museum, on Wednesday evening, June 17th.

The National Telephone Electrical Society.—The second annual conversazione of this society was held at the Colonnade Hotel, New-street, Birmingham, on Friday, May 15th.

Stafford.—Telephone transmitters were recently placed in Christ Church, Birmingham, and receivers in the house of Dr. E. W. Taylor, of Stafford, where the service was followed with the utmost ease.

St. Pancras Vestry.—The Electricity Committee report that satisfactory progress is being made with the works in Stanhope-street, and that preparations are being made to put in the engines and dynamos. Also that the laying of the mains in Tottenham Court-road is progressing satisfactorily.

Boulogne.—Although this town possesses a large gas works the electric light has also been successfully introduced, a large Victoria dynamo, made by the Brush Company, having an output of 370 amperes at 120 volts, being employed to supply a number of the best shops in the town, where the light gives great satisfaction.

The Boy Messengers Company.—Mr. Richard King has now retired from active management of the Boy Messengers Company, which will be managed until it is taken over by the new Boy Messengers and Electric Call Company by the Hon. P. B. Lyon, who for nearly two years has been co-managing director with Mr. King.

Digitized by Google

The Heilmann System of Electric Traction.—M. Heilmann will shortly carry out some experiments with a train equipped according to his system. M. Heilmann's idea, which was alluded to by our Paris correspondent in our issue of March 13th, consists essentially in replacing the ordinary railway locomotive by a 600 H.P. central station on wheels, supplying current to motors geared direct to the axles of the vehicles.

The Telegraph Extensions in Orkney and Shetland.—The telegraph steamer "Monarch" has finished the Pentland Firth cable, which was broken on the Orkney side of the Firth, and communication has again been restored by the direct route to the south. The "Monarch" is now lying off Kirkwall, and will, when the weather moderates, proceed to lay the new cable between Sanday and Westray.

Energy.—Matter, said Prof. Elihu Thomson in a lecture recently delivered at Lynn, was formerly considered as the thing that existed, and force the something that acted upon it. Energy is a term used to express something which we do not always understand. It exists everywhere so far as we know. Matter was considered indestructible. If we admit that energy can act on energy, we have no need of the old matter and force.

A Pulley Covering.—The Burt Pulley Covering Company, of Buffalo, N.Y., have brought out a substance known as Brazilian gum pulley covering. It is applied by means of a brush to the pulley, four coats being put on. After the last coat is on, the gum is allowed to harden for 12 hours, and then the face of the pulley is oiled with castor oil, or any good belt dressing, and the belt put on. This covering is said to prevent slipping of the belt.

Electricity in a Glass Factory.—The Pittsburg Plate Glass Company, of Ford City, Pa., is, says *Industries*, adopting the use of electric motors in its large plant in that city. The Company has a glass-polishing table which is said to be novel, and economical in comparison with similar machines. These tables are over 30ft. in diameter, and are revolved by gearing which has heretofore been operated by steam. The Thomson-Houston Company has now installed a 100 H.P. motor to operate these polishing tables.

Barnsley.—At yesterday's meeting of the Town Council, the following minute was submitted by the Park and Lighting Committee:—"The Committee recommend that in consequence of the withdrawal by the Westinghouse Electric Company of their tender, and of the withdrawal by the Board of Trade of their sanction to overhead wires, and of the large increase thereby occasioned in the cost of supplying electricity to the borough, the consideration of the present scheme be adjourned; and they further recommend that the borough surveyor be directed to prepare a scheme and plan for the supply of electricity to a smaller area, and to submit the same to the consideration of the Committee as early as practicable."

The Manufacture of Submarine Cables in France.—To the many reasons which militate in favour of the "telegraphic emancipation" of France, we may add, says *La Lumière Électrique*, a sad reminiscence of the *année terrible*. The Government having been obliged to quit Tours and take refuge at Bordeaux, communication with the Army of the North was of the slowest character. To overcome the difficulty Gambetta sent an agent to London to purchase a cable to connect Brest with Boulogne. The cable was paid for and taken on board a cable steamer, but at the moment when the vessel was getting under way the representations of the German Ambassador resulted in its detention.

The Societe Francaise des Telegraphes Sous-Marins.—The new network of this Company, starting from the north of Brazil, will run to Cayenne, Paramaribo, Martinique, and Guadeloupe. Thence the system will stretch across to St. Domingo and Cuba. From St. Domingo a cable will be run to Venezuela, touching at Curaçao. Martinique has given the Company an annual subsidy of £2,000 for 25 years, Guadaloupe one of £2,400, and French Guiana one of £4,000, each for 25 years. Dutch Guiana has voted an annual grant of £2,000 for 20 years, and Curaçao has guaranteed the Company a minimum annual income of £3,800 for 25 years. These subsidies amount in all to £14,200, a sum sufficient to pay the interest on the money borrowed by the Company to complete its system.

Science v. Art at South Kensington.—In a letter which appeared in *The Times*, of Wednesday, Profs. Ayrton and Armstrong remark—

> We cannot help thinking that a mistake has been made in calling public attention too exclusively to the housing of the science collections—the extension of the science schools appears to be a far more important matter. . . . The accommodation at present afforded by the Royal College of Science laboratories is not only inadequate, but beneath contempt in comparison with that to be found in Continental cities, such even as Göttingen and Zurich, for example; and those of us who have some knowledge of modern requirements know full well that every inch of space on the Imperial Institute-road side of the block of land on which stands the Natural History Museum will before long be required for the purposes of the Royal College of Science. The intrusion of an art gallery into this space would have a most disastrous effect by irretrievably preventing the proper and natural expansion of the Royal College of Science laboratories. . . .

Bath.—At a meeting of the Town Council last week, Prof. Forbes' report, an abstract of which appeared in our issue of April 24, with the remarks and recommendations of the Electric Lighting Committee, was submitted. The Electric Lighting Committee asked authority to adopt Prof. Forbes' recommendations:—(1) To retain a competent electrical engineer to make periodical visits—once a quarter—in order to test the condition of the circuits, to examine the street lighting, and to note the constancy of the electric pressure of the incandescent lamps; and (2) To authorise them to supply a few additional arc lamps to those parts where the lights are now too far apart. After a long discussion, in which differences of opinion were expressed upon the subject, the report was adopted.

The De Meritens Battery.—At the last meeting of the Société Internationale des Electriciens the report of the Laboratoire Central on the De Méritens battery was read. M. Hospitalier, however, elicited the fact that M. de Méritens had taken the battery under test away with him every evening. He further stated that the battery was really due to Baron d'Ebner, and was exhibited in the Austrian section of the Exhibition of 1867, and was described in the treatise of MM. Cazin and Angot in 1881. Moreover, the battery tested at the Laboratoire Central was not the same as the one tested by him; the zincs were larger in the proportion of nearly 4 to 1, the carbon was suppressed, and a porous pot was added, &c. Making, however, the necessary allowances for these facts, it was easy to see that the results arrived at corroborated those of M. Hospitalier.

Exports of Telegraph Apparatus.—The value of the exports of telegraph wires and of apparatus connected therewith during April was below the monthly average, and was very much less than in the corresponding month of last year. Owing, however, to the large exports in January and March, the figures for the four months still compare very favourably with the exports at the corresponding period of either last year or the year before. The following table gives the details of the value of exports for the four months, in comparison with the corresponding figures for the two previous years:—

	1891.	1890.	1889.
January	£238,223	£71,686	£113,230
February	22,306	201,594	32,086
March	392,552	51,390	285,993
First quarter	653,081	324,670	431,309
April	59,226	187,733	13,032
Four months	£712,307	£512,403	£444,341

Finsbury Technical College. Students' Conversazione.—In spite of the unpropitious weather, this conversazione, which was one of a series which have been held annually since 1885, was a decided success. In the basement a fountain had been contrived, tastefully decorated with palms and various tropical plants, from under which gleamed several prettily-arranged incandescent lamps. In the various rooms of the College representative firms displayed instruments and goods typical of almost every branch of electrical science. Instruction and amusement were alternately provided by a lecture on "Electricity in Motion," by Prof. Silvanus Thompson, who contrived to show a large number of interesting experiments in a comparatively short time, and by a concert given under the auspices of the Old Students' Association. By the courtesy of Dr. Wormel

Digitized by Google

the proceedings concluded with a dance, held in the hall of the Cowper-street Schools, where some "Tableaux Statuaires" had also been provided early in the evening. Altogether, the Students are to be congratulated on the brilliant and successful way in which all the arrangements were carried out.

The West End Street Railway at Boston.—Work on the power house of the West End Street Railway Company of Boston is rapidly progressing, and the station will have over 13,000 H.P. capacity before winter. The station is arranged according to the usual American custom. The engines are arranged half on one side of the house and half on the other. The 28ft. driving pulleys of the engines have faces 10ft. 7in. in width. The power from each driving pulley is transmitted by means of two 5ft. belts, which lead over 7ft. pulleys upon the countershaft, having 5ft. 2in. faces, and running in pairs close together. Upon either side of the receiving pulleys are arranged 10ft. pulleys, having a 32in. face, from each of which a 30in. belt transmits the power to the pulley upon the shaft of the generators, located upon the floor above. The generator pulleys are 4ft. 8in. in diameter, and run at 400 revolutions. Each section of the countershaft is connected by means of clutches, so that when they are all connected there will be two lines of countershaft, each 250ft. in length, the shaft being 9in. in diameter. The entire plant will be duplicated as soon as possible after the first portion is in successful operation. The engines are by E. P. Allis and Co., of Milwaukee; the dynamos being multipolar Thomson-Houston machines. The West End Company have also been experimenting with various motors and trucks. Considerable attention has also been given to improvements in line and track construction.

Curious Electrical Phenomenon.—Some remarkable electrical phenomena accompanying the production upon the large scale of solid carbon dioxide are described, says *Nature*, by Dr. Haussknecht, of Berlin, in the current number of the *Berichte* of the German Chemical Society. In order to obtain large quantities of solid carbonic acid it is found most convenient in practice to allow the liquid stored in the usual form of iron cylinder to escape into a stout canvas bag. The liquid issues at pressures varying from 60-80 atmospheres, and a compact snow-like mass of solid carbon dioxide is formed in the canvas receiver. When the experiment is performed in the dark, the canvas receiver is seen to be illuminated within by a pale greenish-violet light, and Dr. Haussknecht states that electric sparks 10-20cm. long dart out from the pores of the cloth. Dr. Haussknecht further states that the phenomenon is very noticeable in the dark whenever there is a leakage in any portion of the compressing apparatus or the manometers connected therewith. The reason assigned for this development of statical electricity is similar in principle to that usually accepted in explanation of the hydro-electric machine of Sir William Armstrong. As the liquid carbonic acid is issuing from the valve it becomes partly converted into gas, which is violently forced through every pore of the canvas. Moreover, carried along with this stream of gas are great quantities of minute globules of liquid, which are brought in forcible contact with the solid particles already deposited. Dr. Haussknecht therefore considers that the electrical excitation is due mainly to the violent friction between these liquid globules and the solid snow. It is very essential for the successful reproduction of these electrical phenomena that the carbon dioxide should be absolutely free from admixed air; that prepared artificially yielding much finer results than that obtained from natural waters, which latter contains considerable quantities of air. The luminosity is not generally developed in the interior of the receiver until a crust of solid carbonic acid 0·5-1cm. thick has been deposited, which renders the probability of the correctness of the above theory all the greater.

The Manufacture of Insulators.—To obtain a thoroughly efficient insulator the greatest attention must be paid to its design, the quality of the material, and the nature of the glaze. The first process in the manufacture is the preparation of the mixture of the different ingredients, technically called "slip." This mixture, which is of a creamy consistency, is passed through a series of oscillating sieves, and is further stirred with a number of horse-shoe magnets to remove particles of iron. The "slip" having been thoroughly mixed, filtered, and purified, is forced by pumps through a press fitted with canvas bags, with the result that the water is squeezed out, and the clay sediment remains in the bags. This sediment, after being allowed a certain time to mature, is passed twice through a pug-mill, in which it is thoroughly kneaded. The prepared clay, as it comes out, is cut then into lumps, and pounded again, and kneaded by hand. The clay is now weighed out in lumps of a size to suit the insulators to be made The insulators are next roughly shaped by hand, and placed in a heated chamber and allowed to dry partially, till they have become sufficiently solid to admit of handling; they are then said to be in the "green" state. In this "green" state the clay is placed in lathes and turned in slotting and drilling machines; screws are cut, and the insulator is finished true to gauge. The insulators, now in the "white" state, are carefully examined for flaws. The perfect ones are placed in fireclay receptacles called "seggars," and built up inside circular kilns, or ovens, for firing. The process of baking takes from 36 to 48 hours, and great skill is requisite in the process. On removal from the oven the insulators are in what is called the "biscuit" state. They then go to the dipping house to be "dipped" in the glaze. This glaze is an important feature in the telegraph insulator, for while the leakage *through* the insulator depends upon the quality of the porcelain, the surface leakage depends largely upon the glaze. After being "dipped" in the glaze, the insulators are again placed in "seggars," and then passed into the glazing kiln. This completes the manufacture so far as the porcelain part of an insulator is concerned. The cups have next to be fitted with stalks, and are finally electrically tested.

Recalescence in Steel and Iron.—In the current number of the *Philosophical Magazine* Mr. F. J. Smith gives an account of some new methods of investigating the points of recalescence in steel and iron. The object of the experiments was to discover the time-connection which exists between the change of form and the change of temperature. Several methods of experimentation were tried, and the following was the one finally adopted. The upper end of the steel wire to be tested was fixed vertically; the lower end was attached to a long light lever of aluminium, so arranged that a small change of length of the wire caused a large movement of the end of the lever, which traced a line on the smoked surface of paper rotating on an ordinary physiological chronograph cylinder. A platinum-platino-rhodium thermo-couple, twisted round the wire where it was heated, was in circuit with a Deprez-D'Arsonval galvanometer. By means of this combination the temperatures at which the changes of length of the wire took place were read. The movements of the beam of light reflected from the galvanometer were recorded on a moving photographic film. The outcome of the experiments was that the changes of form of the metal under examination took place at the times of change of temperature, so that a curve so traced on the smoked paper can be used as an index of the changes of form and of the changes of temperature. Thinking it probable that these changes might be accompanied by some sounds at the critical points, the following apparatus was constructed:—A mica disc was fitted into a circular recess, turned out of a piece of wood. The steel wire under examination was attached at one end to the centre of the disc, at the other to a vertical post. The front of the recess into which the mica disc was fitted was furnished with two sounding tubes. On heating the wire a certain temperature was reached at which a sharp crackling sound was heard. As the temperature was increased this ceased; then, on removing the flame, at the same temperature at which the first sound was heard, a second similar sound occurred. This took place at the point of recalescence. As the wire cooled this ceased, and then, when a temperature of about 490°C. was reached, a very sharp sound was emitted. This third sound appears to take place at the second critical point observed by M. Osmond. The wire used in these experiments was steel pianoforte wire, annealed and straightened. The last experiment was also arranged so that the steel wire when heated should be in a strong magnetic field. Repeated trials showed that the sounds produced were in no way altered by the fact of the wire being in the magnetic field.

ELECTRIC AND MAGNETIC THEORIES.

BY SILVANUS P. THOMPSON, D.SC.

(*Continued from page 45.*)

§ 7. Returning from these three fundamental cases, consider next the result of altering the arrangement of Fig. 1 so as to include both the A and B coils in the primary circuit. Now, reference to Fig. 1 will show that, when the key, K, is depressed to close the circuit, while the current in A is rising to its full strength, energy is thrown out into the medium, and passes laterally across into B, and there sets up (or *tends* to set up, if the circuit B is not actually closed) a current circulating in the opposite sense, as indicated by the two arrows in that diagram. If now, however, A and B are both inserted into one circuit, as in Fig. 4, there will still be a tendency, while the current is rising in A, for energy to pass from this part of the circuit into B, there to set up an opposing current. But at the same time, owing to the reception of energy from the source (which

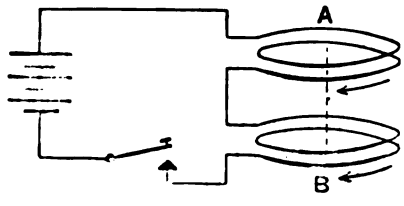

FIG. 4.

affects both A and B, though at present I do not discuss the precise mode), the current is rising in B also, in the same sense as in A. Hence, there is a tendency for energy to be transferred also from B to A, and to set up in A also a current in the sense opposed to that of the actual current. While these actions are going on, the current cannot rise as quickly to its full strength as it would if these actions were absent. And during this time energy is drawn from the battery, which does not manifest itself either in A or in B, but is, for the time being, employed in producing in the intervening medium a state of stress, thereby adding to the potential energy of the system. So long as the current flows around A and B this state of stress is maintained. When the current is stopped by raising the key, K, this energy returns back suddenly from the medium, laterally into the circuit, and appears in the form of light and heat, causing a brilliant spark at the key. These phenomena, *if taken by themselves*, might be compatible with the notion of propagation of

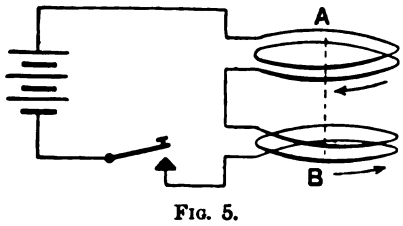

FIG. 5.

the current by longitudinal forces, and the propulsion of the current by an end-thrust, like water in a pipe; for one has only to suppose the current to be endowed with actual inertia to furnish a plausible account of the spark seen on opening the key.

§ 8. But now let us just simply suppose the connections of the coil B to be reversed, as shown in Fig. 5, so that the energy which travels laterally out of A shall now tend to help the current in B to flow, instead of tending to hinder it. It will also follow that the energy travelling laterally out of B to A will help the current in A to rise. As a result the current will rise both in A and in B more rapidly than it would have risen in either coil alone if the other were absent. More of the battery's energy will be directly expended in the conductor in heating it, and less will be stored up in the medium because the medium will not be put under so great a stress. On opening the key the spark at K will be far less than in the previous case, less than if either A or B were present alone.

§ 9. Now, consider by the light of these experimental facts the doctrine of end-thrust. It utterly fails to account for the difference between the two cases of Fig. 4, which produces a great spark, and Fig. 5, which produces practically none. Same coils, same battery, same current, same end-thrust—if there were any such thing at all—same inertia of current running along, like water in a pipe, but not the same spark on breaking. On the hydraulic analogy, with water flowing in a pipe, the two cases are identical, yet they produce wholly different effects. It is clear that the hydraulic analogy fails to account for the facts.

If, on the contrary, it is admitted that energy can be transferred from a circuit laterally into the surrounding medium, and can throw that medium into a state of stress, and can reenter a circuit laterally from the medium when the stress is released, then the facts become intelligible. What end-thrust entirely fails to account for is accounted for so soon as we realise that the energy which is necessary to make a current rise in a wire may be, and is, imparted to it laterally through the surrounding medium.

§ 10. Now let me briefly review these cases up to the point at which we have arrived. In cases 1, 2, and 3, the energy beyond all dispute passed into B through the medium, laterally to the so-called direction of the flow of current. In those cases there was no conducting wire by which the energy could have passed from A to B, and the only conceivable mode of transfer was by the medium. In case 4, although there was a connecting wire joining B to A, energy, nevertheless, passed across the medium as before, and set up a stress in it; and by contrast between case 4 and case 5 it was seen that if energy were merely transmitted by the wire, like water in a pipe, by an end thrust, 4 and 5 would have been identical in their effects, whereas, in fact, their effects are different.

In all these cases we have been dealing with currents of varying strength. We shall have to deal with the case of steady currents flow in the next section.

(*To be continued.*)

THE FRANKFORT ELECTRICAL EXHIBITION.

(FROM OUR OWN CORRESPONDENT.)

The Frankfort Electrical Exhibition was opened on Saturday last under very favourable circumstances.

Leopold Sonnemann, the Chairman of the Committee of the Exhibition, in the course of his address to the Empress Frederick and other invited guests, said that after eight years of rapid progress in all branches of electrotechnology it had been thought good to hold a review of what had been accomplished. In order to give an idea of the extent of the Exhibition in comparison with the previous ones held in Germany, he mentioned that the first German electrical exhibition, in Munich, in 1882, had at its command only 160 H.P.; in the second, at Vienna, in 1883, the horse-power had already risen to 1,200 H.P.; while at Frankfort this year 4,684 H.P. would be in use. The Finance Minister, Dr. Miguel, then declared the Exhibition open.

A brief review of some of the principal features of the Exhibition may be of interest at this moment, more detailed descriptions being deferred until the exhibits are in a more forward state. The boiler-house lies directly behind the great Machinery Hall, and here are 21 boilers of various kinds and sizes, of which 20 are already in use or ready for use; the total heating surface of these is more than 27,500 square feet. Among these may be mentioned two of 2,300 square feet heating surface, each by Steinmüller, of Gummersbach, which provide, through steam engines of a total of 430 H.P., the necessary power for Schuckert and Co.'s dynamos and those of Woodhouse and Rawson, of London. Paucksch, of Landsberg, has three combined boilers of 2,600 square feet heating surface, which serve for the two dynamos of the Helios Company, of Cologne, one of which is of 600 H.P. Simonis and Lanz, of Frankfort, have

Digitized by Google

two boilers of 2,700 square feet heating surface each. A large gallery running round the boiler-house enables visitors to inspect the boilers without disturbing the stokers and attendants.

The great Machinery Hall is, perhaps, the portion of the Exhibition which will attract most attention. Here there are more than sixty prime motors, of which many are already in use. The larger dynamos are mostly coupled directly to the steam engines, especially in the case of firms which build both dynamos and steam engines. In respect of the dynamos exhibited, it is to be noticed that the alternate-current machines are almost as numerous as the direct, and there have evidently been great efforts to obtain examples of the largest types of both kinds. The 100 H.P. dynamo of Edison was thought in 1881 to be excessive, but here we have machines of 300, 500, and 600 H.P.

Siemens and Halske, of Berlin, have undertaken the erection of a central station for the distribution of electric current. They occupy a large space on the extreme right of the Machinery Hall, and their installation will shortly be complete. The direct-current installation consists of a three-cylinder compound steam engine by Kahn, of Stuttgart, and a direct-coupled interior-pole dynamo of 500 H.P. The current will by means of a direct-current transformer be supplied at the necessary pressure for the charging of a battery of 168 Tudor accumulators, having a capacity of 540 H.P. hours, arranged in two parallel rows. A portion of the current, by means of a second transformer, will be used for an electric tramway. The alternate-current installation includes a two-cylinder compound steam engine by Buckau (Magdeburg), to which is directly coupled a 400 H.P. alternator, and an interior-pole machine coupled directly to a steam engine by Daevel, of Kiel. The alternating-current is transformed into a continuous current by a 200 H.P. step-down transformer (2,000-150 volts), to charge accumulators, and by a 100 H.P. and a 50 H.P. transformer to supply current for lighting purposes. By means, also, of four step-up transformers (2,000-20,000 volts), a portion of the current will be delivered for lighting the main Exhibition, the requisite cable being from Siemens Brothers, of London.

Schuckert and Co., of Nuremburg, whose installation is also not quite ready, exhibit several steam engines from 270 H.P. downwards, and many dynamos and motors; they also undertake the lighting of a great part of the Exhibition. The Thomson-Houston Company, of Hamburg, show in the Machinery Hall two dynamos, one of about 40 kilowatts (180 amperes × 220 volts) for transmission of power, and a 17·5 kilowatt machine for arc lamps and glow lamps in series. In the workshops buildings, they have an electro-magnet capable of lifting a weight of one ton, intended for the transport of iron castings in ironworks.

The Helios Company, of Cologne, occupy the central part of the Hall, and, after the Siemens and Halske exhibits, this Company's space will probably prove the most attractive; moreover the greater part of their exhibits are ready. On the south side of the Hall they have a 600 H.P. steam engine by Paucksch, of Landsberg, coupled to a 2000-volt 400-kilowatt alternator. This machine, besides supplying lighting current to the Exhibition ground, will deliver 30,000-watts for lighting purposes at the Palm Gardens at the other end of the town. They have also a 200 H.P. steam engine, by Sulzer, of Winterthur, driving a 2,000-volt 40-ampere alternator, and a direct-current machine giving 65,000 watts at 110 volts. Various other machines are also erected on their site.

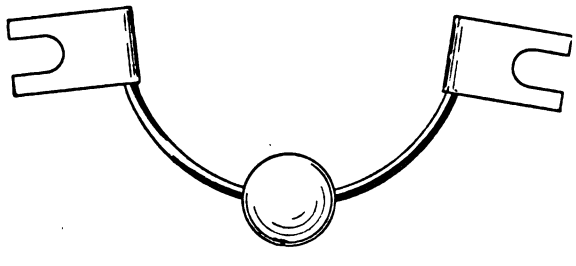
The entire output of the dynamos worked by steam is put down at 3,747 H.P.; those run off gas engines give 203 H.P. Altogether, about 31 firms are showing dynamos, electromotors and transformers, while 20 exhibit steam engines and 12 firms gas engines. The large size of the Machinery Hall prevents overcrowding, and the machines are placed in such a manner as to be of easy inspection by the visitor. The execution of the project for the transmission of 300 H.P. from Lauffen-on-the-Neckar to the Exhibition has unfortunately been delayed. It was found that the necessary transformers and insulators could not be procured in as short a time as was anticipated. The two firms which have undertaken the scheme, namely, the Allgemeine Electricitäts Gesellschaft, of Berlin, and the Maschinenfabrik of Oerlikon, have, however, bound themselves under penalty to have the system in working order by August 15. There seems, then, no doubt that this important experiment, which is awaited with so much eagerness, will be carried out. The manufacture of the conductors is already commenced by the Post Office authorities, and the 10,000 large insulators which will be necessary have been ordered. It will be remembered that the electricity is to be generated by means of an alternator driven by water-power on the Neckar, and that the current is to be generated at a pressure of 50 volts, transformed up to 25,000 volts, and transmitted by three wires of 4mm. thickness across the 110 miles of country separating Lauffen from the Exhibition.

After the Machinery Hall we come to the department for the Distribution of Electricity, which has a separate building devoted to it at the back of the Machinery Hall. The exhibits here are not ready. Here are shown transformers, both alternating and direct, of all kinds, pressure regulators, automatic rheostats, &c. Running down either side of this are the workshops, the motive power of which is derived from the Machinery Hall. The technical arrangements of these workshops are in the hands of Engineers Sarasin and Stahl. Some 35 motors of different types, and varying from $\frac{1}{15}$ to 25 H.P., are at work. The current is derived from three sources—partly from the main Machinery Hall; partly from the electrical station set up at the Palm Gardens, distant about three-quarters of a mile; and the rest is transmitted from Offenbach, about seven miles up the Main. From the two last-mentioned places the current is transmitted overhead at a high pressure, and transformed down to the necessary low pressure. One of the most interesting of the workshops will be the glow lamp manufactory, of Maatschappy, Gelnhausen; and another the manufacture of small lathes and clocks, &c., by Wolf, Tahn and Co., of Frankfort, small Hartmann and Braun motors being used.

Finally, on the left of the Machinery Hall, a large pile of earth has been heaped up, on one side of which is a large pond, with an artificial waterfall running into it down the side of the mound, which produces beautiful effects when lighted up from underneath by electricity. On the top of the mound is a convenient restaurant, with a tower illuminated by numerous glow lamps. A model mine is arranged under the mound, with underground electric railway, electric boring machines, &c., and lamps which ought to make gas explosions out of the question.

AN IMPROVED FUSE.

The weak point about the fuses in ordinary cut-outs is in the attachment to the terminals. The tin wire generally used is excellent as far as easy and prompt melting is concerned, and it is



Improved Fuse.

free from oxidation, but it is too soft to afford sufficient resistance to the pressure of a screw head or clamp. If eyelets are used, the screw must be completely removed, and the eyelets and screws do not always agree in size. Sir David Salomons has sent us a specimen of a fuse which we illustrate herewith. The ends of the tin wire are held in clamps of sheet copper about 15 mils in thickness, affording a contact of large surface. The slotted hole enables the copper contact piece to be easily removed by only slacking back the screw half a turn or so. The idea is not patented, and we are asked to publish it in order that no one else may patent it.

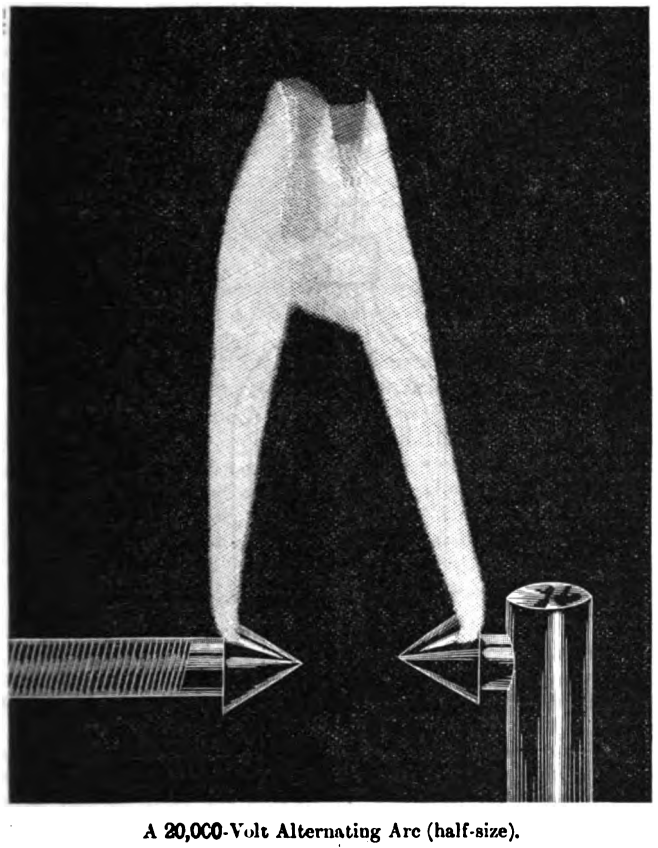
EXPERIMENTS WITH HIGH-TENSION ALTERNATING-CURRENTS.*

Messrs. Siemens and Halske, of Berlin, recently invited the members of the Elektrotechnishe Verein of that city to their works to witness the demonstration of a series of experiments on alternating-currents under a pressure of 20,000 volts. In order to show that the desired pressure was really *en evidence*, the high tension was conducted through a pair of wires of only 0·2 mm. diameter to a battery of 200 100-volt incandescent lamps, all connected up in series. An ordinary Siemens electric light cable was inserted, and broke down at a pressure of some 15,000 volts.

At the end of the meeting a few experiments on the formation of the arc under this enormous pressure were shown. The sparking distance varied considerably according to the shape of the electrodes. At 20,000 volts a spark jumped from a ball to a ball about 10 millimetres, while between two points a sparking distance of 30 millimetres, and sometimes even more, was reached. This arc is shown half size in the accompanying engraving.

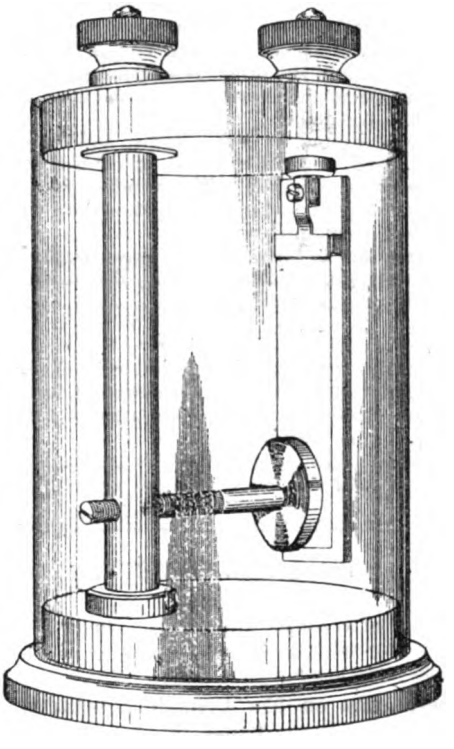


A 20,000-Volt Alternating Arc (half-size).

The arc which followed the jumping over of a spark made a loud humming and clapping noise, and flapped about, being easily carried away by the slightest draught. The arc could be drawn out horizontally to something like 100 millimetres distance between the electrodes, and even to a distance of 150 millimetres, when carbon pencils were used as electrodes, but it always remained standing up in a point.

AN ELECTROSTATIC SAFETY DEVICE.

This device, as shown in the accompanying illustration, is a glass cylinder fixed on an ebonite base, and closed at the top by an ebonite cap. A solid brass rod runs from top to bottom, and near the bottom, and at right angles to it, is fixed a smaller adjustable rod, terminating in a flat head. Opposite to this flat disc there is a brass strip secured to the ebonite cap. From the top of this brass strip hangs a gold or aluminium foil. The foil and strip are placed to earth, and the solid brass rod is connected to the circuit to be protected. Should the difference of potential between the foil and the terminal opposite to it attain more than a certain amount, electrostatic

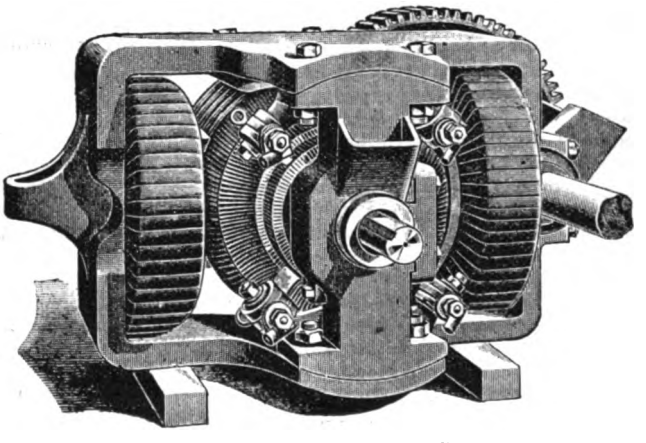


attraction will cause the foil to touch the disc, and place the circuit to earth. The apparatus, which is a modification of the Cardew earthing device, is constructed by Messrs Drake and Gorham, of Victoria-street.

* From the *Electrical Engineer* of New York.

THE NEW EDISON SINGLE-REDUCTION STREET CAR MOTOR.*

In the accompanying illustration is shown the new multipolar single-reduction gear street car motor, recently brought out by the Edison Company of America. The motor is of the 4-pole type, and practically iron-clad. Only two poles, those in the horizontal



New Edison Single-Reduction Street Car Motor.

plane, are wound with coils. The entire field-magnet frame, consisting of special soft cast steel, is made in one casting, with the exception of the pole-pieces, which are attached by screw bolts after the spools have been slipped on over the straight cores at the sides.

In the construction of the machine the facing of the armature bearing and the cylindrical armature space are bored out at one

* From the *Electrical Engineer* of New York.

Digitized by Google

boring, and by loosening two bolts the armature can be slipped out completely, so that inspection can be effected with great facility. The armature, which is of the Gramme type, is built up of punched soft iron rings insulated from each other, and with the end plates of wrought iron and bevelled.

The diameter of the armature is 18in., and its length 13in. The shaft is 3in. in diameter, and upon each end is mounted a pinion which meshes with the large gears at each end of the axle, thus equalising the power on the axle. One end of the magnet forms the car axle bearing, and the other is suspended by a spring at the nozzle for easy starting. The commutator has been made specially large, being 10in. in diameter.

The armature is wound in 140 sections, and on account of the strong field employed, and the method of connection to the commutator, no spark is observed. The winding is put on in one continuous length of wire, and at each section a tap wire of German silver is taken to the commutator.

The entire machine is encased in a water-tight cover, and its total weight, with gears, is 2,200 pounds. The machine is rated at 25 H.P., but will readily develop 30 H.P. It is intended to apply two of these machines to each car of the double truck type, while one machine alone will be ample to drive the smaller cars. The motor is of the series type, and the regulation is effected by varying the combination of the fields, which are wound in three sections. The four carbon brushes employed are rigidly fastened to the frame, and require no shifting throughout the range of load to which the motor is subjected. The motor is calculated to revolve at 460 revolutions with the car running at a speed of 12 miles an hour.

PHYSICAL SOCIETY.

At the meeting of the Physical Society, held at Cambridge in the Cavendish Laboratory, on Saturday, May 9th, the following communications were made :—

"Some Experiments on the Electric Discharge in Vacuum Tubes."

BY PROF. J. J. THOMSON, M.A., F.R.S.

The phenomena of vacuum discharges were, he said, greatly simplified when their path was wholly gaseous, the complication of

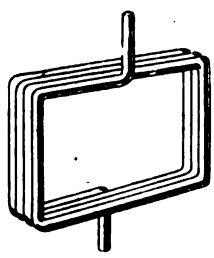


Fig. 1.—Coil of glass tube for vacuum discharge experiments. The primary coils are filled with mercury, the secondary coils form continuous closed circuits.

the dark space surrounding the negative electrode and the stratifications so commonly observed in ordinary vacuum tubes being absent. To produce discharges in tubes devoid of electrodes was, however, not easy to accomplish, for the only available means of producing an electromotive force in the discharge circuit was by electro-magnetic induction. Ordinary methods of producing variable induction were valueless, and recourse was had to the oscillatory discharge of a Leyden jar, which combines the two essentials of a current whose maximum value is enormous, and whose rapidity of alternation is immensely great. The discharge circuits, which may take the shape of bulbs, or of tubes bent in the form of coils, were placed in close proximity to glass tubes filled with mercury, which formed the path of the oscillatory discharge. The parts thus corresponded to the windings of an induction coil, the vacuum tubes being the secondary and the tubes filled with mercury the primary. In such an apparatus the Leyden jar need not be large, and neither primary nor secondary need have many turns, for this would increase the self-induction of the former and lengthen the discharge path in the latter. Increasing the self-induction of the primary reduces the E.M.F. induced in the secondary, whilst lengthening the secondary does not increase the E.M.F. per unit length. Two or three turns (Fig 1) in each were found to be quite sufficient, and, on discharging the Leyden jar between two highly-polished knobs in the primary circuit, a plain uniform band of light was seen to pass round the secondary. An exhausted bulb (Fig. 2) containing traces of oxygen was placed within a primary spiral of three turns, and, on passing the jar discharge, a circle of light was seen within the bulb in close proximity to the primary circuit, accompanied by a purplish glow, which lasted for a second or more. On heating the bulb the duration of the glow was greatly diminished, and it could be instantly extinguished by the presence of an electro-magnet. Another exhausted bulb (Fig. 3), surrounded by a primary spiral, was contained in a bell-jar, and when the pressure of air in the jar was about that of the atmosphere the secondary discharge occurred in the bulb, as is ordinarily the case. On exhausting the jar, however, the luminous discharge grew fainter, and a point was

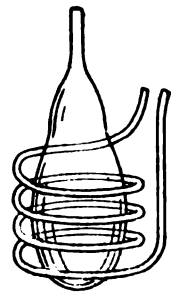

Fig. 2.—Exhausted bulb surrounded by primary spiral consisting of a coiled glass tube containing mercury.

reached at which no secondary discharge was visible. Further exhaustion of the jar caused the secondary discharge to appear outside the bulb. The fact of obtaining no luminous discharge either in the bulb or jar the author could only explain on two suppositions, viz., that under the conditions then existing the specific inductive capacity of the gas was very great, or that a discharge could pass

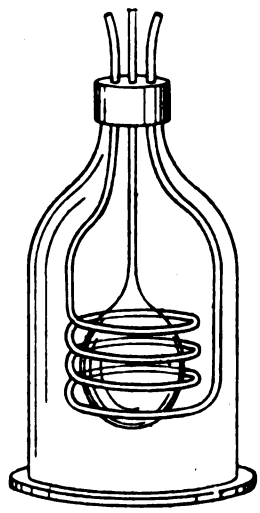

Fig. 3.—Exhausted bulb surrounded by primary coils, enclosed in bell jar.

without being luminous. The author had also observed that the conductivity of a vacuum tube without electrodes increased as the pressure diminished until a certain point was reached, and afterwards diminished again, thus showing that the high resistance of a nearly perfect vacuum is in no way due to the presence of the

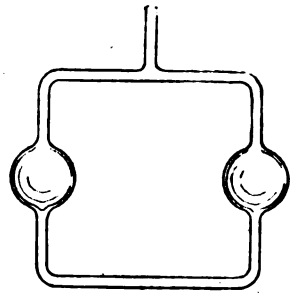

Fig. 4.—Exhausted secondary coil of one loop containing bulbs. The discharge passed along the inner side of the bulbs, the primary coils being placed within the secondary.

electrodes, One peculiarity of the discharges was their local nature, the rings of light being much more sharply defined than was to be expected. They were also found to be most easily produced when the chain of molecules in the discharge were all of the same kind. For example, a discharge could be easily sent through a tube many

Digitized by Google

feet long, but the introduction of a small pellet of mercury in the tube stopped the discharge, although the conductivity of the mercury was much greater than that of the vacuum. In some cases he had noticed that a very fine wire placed within a tube on the side remote from the primary circuit would prevent a luminous discharge in that tube.

"Some Experiments on the Velocities of the Ions."

BY W. C. D. WHETHAM, B.A.

In studying electrolysis, the question as to whether there is any transference of solvent when a porous wall is absent presented itself to the author. The ordinary methods of testing for transference, such as by increase of pressure, or by overflow, not being available, when there is no diaphragm, the author used different coloured solutions of the same salt, such as cobalt chloride in water and in alcohol, the former of which is red and the latter blue. By putting the solutions into a kind of U-shaped tube (Fig. 5), any change

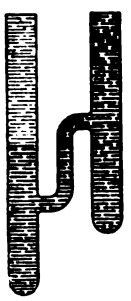

FIG. 5.—U Tube for measuring velocities of ions.

in the position of the line of junction of the two liquids could be measured. Two aqueous solutions in which the anion was the same were also tried, one combination being cupric chloride and common salt, and in this case the line of demarcation traversed about 7in. in three hours. The results hitherto obtained by this method agreed fairly with those found by Kohlrausch.

'On the Resistance of some Mercury Standards."

BY R. T. GLAZEBROOK, M.A., F.R.S.

In 1885 M. Benoit, of Paris, supplied the author with three mercury standards, nominally representing the Paris Congress ohm, now commonly known as the legal ohm. Tests of these standards were described in a Paper read before the Physical Society in 1885 by the present author. Recently he had occasion to compare two of the standards with the British Association coils. The mean of many concordant results gave the resistance of one of the mercury standards (No. 37) as 1·01106 B.A.U.; whilst that of the other (No. 39) was 1·01032 B.A.U. Expressing them in legal ohms the present resistances are (No. 37) ·99986 and (No. 39) ·99913, whilst in 1885 the values obtained were (No. 37) ·99990 and (No. 39) ·99917. This shows that within the limits of experimental error the ratios of the mercury standards to the B.A. coils have remained practically unchanged during six years. The numbers given above are based on Lord Rayleigh's determination of the specific resistance of mercury which differs appreciably from that found by Mascart and other observers. Taking the mean of the later concordant determinations the value of the mercury standards expressed in legal ohms become (No. 37) 1·00033 and (No. 39) ·99959. The values given by the maker were 1·00045 and ·99954 respectively, showing a very close agreement. The author also found that refilling No. 37 from the same sample of mercury produced no appreciable change in its resistance whilst No. 39 was somewhat affected by a similar operation. Experiments on the co-efficient of increase of resistance of mercury with temperature gave the value ·000872, as the mean co-efficient between 0° and 10° C., a number rather less than that obtained by Kohlrausch.

DISCUSSION.

In the discussion on Prof. Thomson's Paper, Prof. FITZGERALD said the beautiful experiments were likely to lead to very important results. He did not quite understand how placing a fine wire in a vacuum tube could prevent the luminous discharge; for, if the wire was on the side remote from the primary, and if there was any great increase in specific inductive capacity, he would have expected the air to screen the wire.

Prof. LODGE asked for further information as to the action of the magnet in preventing the afterglow, and in some cases precipitating a luminous discharge. The experiment with the exhausted bulb within the bell-jar was also difficult to understand, and he did not see why one of Prof. Thomson's two suppositions must necessarily be true.

The PRESIDENT (Prof. Ayrton) inquired whether Prof. Thomson had tried Mr. Crookes' experiment, in which the electric pressure necessary to produce a discharge was greatly lessened by putting a phosphorescent material in the tube.

Prof. THOMSON, in reply, said he had not tried the experiment, but the phosphorescence he had observed was of quite a different character to that produced in Mr. Crookes' tubes. To Prof. Fitzgerald he said the action of the wire was probably a question of time, and thought the whole field was in some way thrown on the wire, and thus discharged. In reply to Prof. Lodge, he had not ascertained the true nature of the effect of a magnet on the glow; but he believed the glow to be due to a combination which might be prevented or facilitated by the action of the magnet causing the density to be different in different parts of the bulb.

On the motion of Prof. AYRTON, seconded by Prof. RUCKER, a hearty vote of thanks was accorded to the authors for their valuable and interesting communications, and for the kind manner in which the Society had been received and entertained by the Cambridge members. Prof. Thomson and Mr. Glazebrook acknowledged the vote.

ON THE MOST ECONOMICAL MODE OF FEEDING A LOW-PRESSURE NETWORK.*

BY R. E. CROMPTON, VICE-PRESIDENT.

The advocates of alternating transformer (hereafter called the A.T.) system of distribution, appear at last to be in agreement with those who designed low-pressure systems, in that they admit that for the supply of towns of ordinary compactness a low-pressure network must be provided. Their practice in the future is to diverge from their practice in the past, in that they fix the transformers only at the feeding points of the network, instead of in each of the consumers' houses. In other words, they propose to use high-pressure feeders, consisting of cables carrying a high-pressure primary current, transformed so as to supply a low-pressure network on either the two or three-wire system, by a transformer fixed at the feeding point. Mr. Ferranti, Mr. Gordon, and other gentlemen advocate banking the transformers at these feeding points, and the use of automatic apparatus to switch their transformers in as the load requires. Others, such as Mr. Mordey, prefer to spend more money on the perfecting of a design of a single transformer at the feeding point, so as to avoid the complication of automatic apparatus. As it was evident that there is a certain length of feeder at which the low-pressure direct system fails to compete successfully in first cost and that of up-keep with the above-described high-pressure A.T. feeder, I have recently investigated the question in order to find out at what mean length of feeders the low-pressure and high-pressure systems compete on equal terms of first cost, cost of up-keep, and efficiency. The result of my investigation is to show that when a three-wire low-pressure system, distributing direct to 110-volt lamps, is compared with an A.T. system, distributed by 2,000-volt feeders, transformed to supply the same three-wire network, the average annual efficiency of the feeders in both cases being 90 per cent., the low-pressure feeder is cheaper for all distances up to 2,400 yards, each of the feeders being calculated to supply 100 kilowatts; and the annual cost for up-keep, including a sum of 5 per cent. for interest on the capital, will be about £290 per annum. These large figures lead me to compare with them the known cost of up-keep of feeders carrying the same load which are now in use in London. I find that feeders of an average length of 600 yards cost about £300 each, and for interest and up-keep £25 per annum. This comparison shows that if we increase the length of each feeder by 1,800 yards, or say one mile, it increases the supply company's annual up-keep charges by not less than £260 per annum per feeder. If we apply these figures to a company supplying a district of about a square mile, which, if it had within it two generating stations, could feed its network with 10 short feeders, and substitute for these two central stations, one external generating station one mile distant from the outside of the district, the extra cost of up-keep of the 10 long feeders will be £2,600 per annum. At a load factor of 10 such a district would sell 876,000 units per annum; therefore the above sum of £2,600, divided by this number of units, is equal to 0·72 of a penny per unit sold. Now, even at present the cost per unit for coal and ground rent (which are the only two items affected by the removal of the site from a central position to a distant point) only slightly exceeds 1d. a unit, and in all probability during the present year this figure will be brought down to a sum approximately the same as the above-mentioned up-keep of the feeders, viz., 0·72, which I have shown is the actual cost of up-keep of the feeders only. This shows the absurdity of imagining that any saving can be effected by this mode of feeding a network, and it is quite evident that those who have advocated the system have never seriously looked at the matter from this point of view. In such cases where really great savings can be effected by generating the

energy at a distance from the district to be supplied, as in the case of water power, Mr. Ferranti's original Deptford scheme of supplying one or two large transformer stations by currents of very high E.M.F. is in all probability the right one; but the distribution must be modified from Mr. Ferranti's original intention: that is to say, he need not transform twice, but merely supply several transformer stations by his high-pressure mains, and feed the surrounding districts by not only a low-pressure network, but also low-pressure feeders. I have not at command the figures as to the cost of mains of extreme high pressure such as Mr. Ferranti advocates; but I have no doubt that he will be able to show, even for such distances as one or two miles, a very considerable saving on the separate feeder system that I have just criticised.

Table I. shows you the details of first cost of the 600 yards low pressure, 2,400 yards low pressure, and 2,400 yards A.T. feeder with transformer.

Table II. shows the details of cost of up-keep of the same three feeders. It will be noticed I have taken the cost of up-keep on excavation or concrete work below ground at 1 per cent. per annum, on the transformer pit at 2½ per cent. per annum, on the bare copper at 1 per cent, on both low and high-pressure cables at 8 per cent.; although I might well claim that the cost of up-keep of the high-pressure cable would be a higher percentage on its first cost than the low. The transforming and switching apparatus I have taken at 10 per cent., and I have added a small charge for the up-keep of surface and inspection boxes. This is taken without reference to pressure, in proportion to the length laid. The cost of the low-pressure feeders has been carefully taken out in accordance with our London practice, and that of the high-pressure feeder has been taken out from estimates received from cable and transformer makers. I believe that these figures may be said to be sufficiently correct to make the comparison a fair one; at any rate, I think no one will venture to say that either the first cost or up-keep is taken at too high a figure. For the purposes of my argument they are sufficient to show that 100-kilowatt feeders of 2,400 yards long cannot be put down at less than £1 a yard, and cannot, including transformers, be maintained at less than 2s. 4d. a yard per annum.

The Electrical Manufacture of Phosphorus.—Dr. Readman, at the May meeting of the Glasgow Section of the Society of Chemical Industry, gave a description of the new works and plant which have been erected at Wolverhampton for the manufacture of phosphorus by the Readman-Parker patents. The process consists in decomposing the mixture of phosphoric acid, or acid phosphates and carbon, by the heat of the electric arc imbedded in the mass.

RAILWAY TRAIN-LIGHTING.*

BY WILLIAM LANGDON.

The author stated that the desirability of a better illumination of railway carriages had been long felt. The lamps originally provided were intended simply to enable passengers to enter and leave the carriages without inconvenience, but the exigencies of the present time called for the additional luxury of a reading light. The illuminants in use were rape oil, paraffin oil, compressed gas, and electricity, and the author dealt with the recent advances which had been made in connection with the last.

In October, 1881, a Pullman car, running between Victoria and Brighton, was lighted by electricity, and the experiment was so far successful that it was extended to the entire train, and at present there were 16 trains so lighted belonging to the Brighton Company. Mr. Houghton, the Company's electrician, and the late Mr. Stroudley, were the pioneers of the application of electricity to this purpose. An interesting experiment, devised by Mr. W. H. Preece, was tried on the London and South-Western Railway in 1883-4. The movement of the train was employed to compress air into a chamber, and the air so compressed was used to drive a dynamo to furnish the current for the lamps. In July, 1886, the Great Northern Railway applied electric light to one of their metropolitan trains. The Taff Vale and Cheshire lines had also made experiments in the same direction. In all these cases the lighting was effected by means of a dynamo driven from the axle of the guard's van combined with accumulators stored in the same vehicle. In August, 1884, the London and North-Western Railway tried a different principle in fitting up a short train which was still running between Manchester and Liverpool. The current was produced by a dynamo driven by a Brotherhood engine fixed to the tender and supplied with steam from the boiler of the locomotive.

In this, however, as in the previous cases, the lighting was effected from one point, and should the train be broken up the part severed from the source of current would be left in darkness. In 1888, the Directors of the Midland Railway authorised the equipment of two trains to run between London, Manchester, and Liverpool, in which the following conditions were to be fulfilled, viz.:—(1) Each vehicle was to carry its own lighting power. (2) Each vehicle was to be capable of being coupled and uncoupled and turned about as needed, without the possibility of the connections being wrongly made. (3) The coupling must readily draw apart when coaches were slipped *en route*. (4) The act of drawing the coupling apart must make all the changes in the connections necessary to transfer the lamps from the dynamo circuit of the train to

* Abstract of a Paper read before the Institution of Civil Engineers, May 5, 1891.

Digitized by Google

the accumulator circuit of the carriage itself. (5) Each compartment was to carry not less than two lamps. (6) The lighting throughout the train was to be capable of being turned on or off from any one of the guard's vans. For the sake of experiment, one of these trains was equipped on the "parallel" system, the other on the "series" system. The former, having proved the best, had been adopted by the Company, and there were now five trains leaving St. Pancras daily which were electrically lighted, and in which the dynamo was driven off the axle of the guard's van, each vehicle being provided with accumulators capable of supplying the necessary current without the assistance of the dynamo.

There was also a local train travelling between Manchester and Stockport lighted after the plan adopted by Mr. Houghton on the Brighton line, but equipped with two sets of accumulators and two dynamos driven from the axle. In addition to the foregoing, there were two trains running between London and Bedford, the dynamos of which were driven by small high-speed engines placed on the locomotive.

Dynamos.—The first trains fitted on the Midland Railway were furnished with machines giving a practically constant output of current, no matter how few or how many were the carriages attached. Messrs. Holmes and Co., of Newcastle, had since succeeded in making a dynamo which afforded a current proportional to the resistance of the circuit, and these machines were employed on all main line trains in which the dynamos were driven from the axle.

Accumulators.—These were of the "E.P.S." type. With main-line trains, where each vehicle carried its own batteries, the type employed was C 15 for the larger, and C 11 for the smaller carriages. In all cases the electrical pressure was 35 volts, so that 18 cells were necessary for each.

Electrical Coupling.—Where trains were not broken up, the difficulty of providing an efficient electrical coupling was not so great, but where the marshalling of carriages had to be smartly dealt with at terminal or intermediate stations, the coupling must be such as not only to provide a good electrical connection, but to admit of easy handling. The form adopted by the Midland Company effected these objects in a perfectly satisfactory manner. On a coupling being separated, the lights were automatically turned on. If the lamps were not required, the coupling, instead of being allowed to hang down, was placed upon a "dummy," the effect of which was to turn the current off. For slip coaches special provision was made.

By the insertion of a small resistance in each battery parallel, a fair distribution of the current throughout the different vehicles was attained, and in order to meet the increased pressure when the dynamo was in circuit, a sufficient additional resistance was automatically introduced. The lamps were of 8 c.p., and there were two in each compartment.

With regard to the second mode of generating the current, namely, by dynamos placed on the locomotive, it was believed that at present no other trains save the three already referred to were equipped in that way.

The total number of electrically-lighted vehicles now in operation on the Brighton, Great Northern, and Midland systems was 365 coaches and 57 vans.

In conclusion, the author pointed out that the main points to be determined were whether electricity was safe, reliable, and less costly than other illuminants. The fact that electrically-lighted trains had now been running for a considerable period without accident would appear conclusive evidence of its safety, and experience had shown that there was no reason to doubt its reliability where efficient provision had been made; and the author believed that, when the cost of applying any of the illuminants, whether oil, gas, or electricity, to a complete railway system was taken into account, the latter would be found the most economical. The cost of oil was between ½d. and 1d. per lamp per hour. So far, compressed gas had never been employed for lighting the entire stock of any railway, with the exception of the Metropolitan Railway—which was specially adapted for its application. To consider the cost as applied to stock devoted to certain traffic would hardly afford a true basis of comparison. Where gas was used entirely, depôts must be established at each point at which trains were made up, whilst at busy centres it would probably have to be conveyed some distance by pipes laid down for the purpose. The cost of fitting coaches for gas varied from £4. 8s. to £7 per lamp, while for electricity it was £4. 3s. 4d. per lamp. For trains running which were not broken up on the journey the cost per lamp amounted to £3. 12s. Vans with dynamos cost from £250 to £300 each. Statistics were given showing that the cost for maintenance in the case of gas was from ·045d. to ·250d. per light per hour. There was reason to believe that the total cost of compressed gas, when applied to an entire system, would exceed ½d. per lamp per hour, while the actual cost for electricity, as used on the Midland Railway, had not greatly exceeded ½d. per lamp per hour.

THE TELEPHONE AS AN OPTICAL CURRENT MEASURER.*

BY MAX WIEN.

The author arranges his "optical telephone" as follows:—A thin corrugated German silver membrane, such as is used for aneroid barometers, is provided at the middle of that side which is towards the electro-magnet with a piece of soft iron and on the other side with a pin. The latter presses against a piece of very fine watch-spring steel, one end of which is fixed, whilst the other carries a very light mirror. A telescope is used to throw the image of an illuminated slit on the mirror.

If a constant current is allowed to pass through the apparatus, the membrane changes its position of equilibrium; the beam of light is displaced, and remains so so long as the current does not alter. This displacement is proportional to the current intensity, and can be experimentally regulated. Since the telescope allows 100 divisions of the scale by tenths to be observed, and one division may be made to correspond to about 5×10^{-5} amperes, a conclusion as to the sensitiveness attainable can be arrived at.

Although the "optical telephone" is thus highly suited for constant currents, it is still better adapted for those which alternate. If a simple sine current passes through the apparatus, the membrane vibrates and with it the mirror. Instead of an ordinary displacement a band of light is then produced, the breadth of which is a measure of the amplitude of the sine current.

It is, however, necessary that the natural tones of the membrane and the spring and the number of alternations of the sine current should be in correspondence with one another. This may be easily effected so far as the membrane and the spring are concerned, and also for the current, if the latter is derived from an induction coil, the contact breaker spring of which is brought to the right tone.

By comparing the results with those given by a dynamometer, the proportionality between the displacement and amplitude of the current was experimentally established. The author shows how with his apparatus he has measured self-induction and fluid resistance with alternating currents. Finally, he gives a table showing the conductivity of dilute sulphuric acid of specific gravities between 1·200 and 1·250. The maximum value $691{\cdot}9 \times {\cdot}10^{-7}$ is reached at a temperature of 17·3° C. at a specific gravity of 1·224.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

FRIDAY, May 22nd. (To-night.)

PHYSICAL SOCIETY OF LONDON.

5 p.m. Papers to be read: (1) "Dr. Schobben's Form of Lantern-Stereoscope," by C. J. WOODWARD, B.Sc. (2) "A Simple Steam-Engine Indicator accurate at any speed," by Prof J. PERRY, F.R.S. (3) "Mr. Blakesley's Method of Measuring Power in Transformers," by Prof. J. PERRY, F.R.S. (4) "Alternate Current and Potential Difference Analogies in the Methods of Measuring Power," by Prof. W. E. ELECTRICAL DISCHARGES IN VACUA.

The experiments shown by Prof. J. J. THOMSON before the Physical Society, on the occasion of its most enjoyable excursion to Cambridge, form a new departure in the very interesting study of electrical discharges in vacua. The early researches in this direction served rather to enwrap in mystery the action of the luminous discharge in vacuum tubes. The dark space at the negative electrode, and the varied forms of striæ which appear to have their origin at the positive pole; the difference of potential required to produce a discharge under various degrees of exhaustion; the thermal and magnetic effects, and numerous other beautiful experiments have been minutely examined by GASSIOT, PLÜCKER, DE LA RUE, MÜLLER, and others, while the, as it were, artificial production of stratified discharges, and the curious sensitive state of vacuum tubes, has formed the subject of a very interesting research by SPOTTISWOODE and MOULTON. Even then the examination of the discharge in vacua was left in a very undeveloped condition, and when Prof. SCHUSTER dealt with the subject of the discharge of electricity through gases before the Royal Society, only about a year ago, in his Bakerian lecture, he threw out several bold speculations as to chemical actions in the dark space, and suggested, without any fear of contradiction, that the striæ were due to decomposition, diffusion of ions, and subsequent recombination. A modification of these views has indeed been put forward also by Prof. J. J. THOMSON.

Prof. CROOKES' researches, which have been spread over so many years, and have recently, in their collected shape, formed the subject of his presidential address, have not consisted in

Digitized by Google

the investigation of electrical discharges under natural or forced conditions, but in the utilisation of them as a means for studying the fourth or radiant state of matter, and the behaviour of molecule streams and other kindred phenomena. In this respect, as well as the accidental coincidence that he dispensed in certain cases with actual electrodes, the experiments of Prof. CROOKES compare with those of Prof. J. J. THOMSON. The latter has been using vacuum tubes for carrying out researches of a very different character to those of DE LA RUE and SPOTTISWOODE, and has, indeed, dispensed with the tube form, and induces or produces the discharge in mid air, or rather in mid vacuum. But the work of the two present investigators suggests contrast as well as comparison. Both sets of experiments are of great interest, both are very pretty. Neither of them are of any practical use, and may therefore be studied in scientific tranquility, undisturbed by the company promoter or the prospectus writer. But the one research is pervaded with a mathematical and the other with a chemical instinct. The former tends directly to quantitative results and the latter to qualitative. It is difficult to say if one is more definite or tangible than the other. Both are seasoned with a little controversial animus, for Prof. CROOKES triumphantly pointed to the absence of electrodes, as disproving Dr. PULUJ'S electrode matter hypothesis; while Prof. J. J. THOMSON successfully refutes the strange doctrine that a perfect vacuum is a perfect conductor. On the whole, perhaps, the experiments shown in the Cavendish Laboratory, pervaded as they were by the mathematical spirit of the place, appeal more forcibly to, and are more suggestive for most physicists, if only because they are of a less transcendental order.

Electrical discharges through more or less attenuated gases afford one of the most promising directions in which we may study matter, ether, and, if it be not already abandoned as an entity, electricity. Hitherto these discharges have been very much complicated by the disturbing effect of the electrodes, so much in fact that in many cases there is little else than the terminal effects to be seen. Prof. J. J. THOMSON has, however, not only got rid of the conducting wires, as Prof. CROOKES has done, but he has treated the vacuum tube in an altogether new and effective way. It has hitherto been customary to include a vacuum tube in part of a circuit, but here, by making it the secondary of a transformer or induction coil, it forms a complete, closed, and self-contained circuit in itself. The elimination of the electrodes has an important bearing on the conductivity of a vacuum. Air at ordinary pressures is commonly treated as our best and practically perfect insulator; but when rarefied, it has an apparent conductivity which increases to a maximum, as in the condition of ordinary vacuum tubes, and then diminishes enormously as a true vacuum is approached. This is an instance of the danger of attempting to extend hypothesis beyond the limits of actual observation, for, if good air-pumps had not been invented, it might have been imagined that the resistance of a vacuum was practically nothing, and, by the dangerous principle of symmetry, that it *was* nothing. So tempting was this idea, that the doctrine to which we have referred has been seriously put forward, and it has been suggested that the surface of the electrodes entirely accounted for the resistance. Such a resistance has been observed in a very striking manner in the simple experiment described in the report of the Paper which will be found in another column. We have spoken of the conductivity as apparent, and intended this guarded expression to apply rather to that which is conducted, for the discharge in a rarefied gas does not behave as a current. It has been shown by DE LA RUE that it does not obey Ohm's law. If a double route be provided, it will not divide itself as a current would do, in two portions, proportioned to the conductivities, but it selects one route.

A vacuum discharge is not then a case of simple conduction. SPOTTISWOODE and MOULTON say "one terminal does not feel the electric state of the other directly, as would be the case were they metallically connected, but pours forth its electricity in the shape of free electricity, and leaves it to wander at its own will in that shape." If it could thus wander in a simple straight tube, what might it be expected to do in a mere bulb with no terminals at all? It has a definite direction, as has been proved by the 50ft. vacuum tube at the Cavendish Laboratory, and this supports, to some extent, the conventional idea of an electric current. Strange to say, the discharge in a bulb surrounded by a "primary coil" is manifested in the form of a luminous ring, and that not a broad one; it is accompanied by a lingering glow, unless the bulb be warmed. But it here again behaves unlike a current, and, selecting the path of least resistance or of greatest stress, the *whole* of the discharge takes place along that route, perhaps because it is there that a path is broken through. There is no finite lineal current, but an endless ring, presenting the old puzzle of electromotive force without difference of potential or voltage. The lines of force encircling a current are commonly regarded as a consequence, not as a concurrence, and are usually unimportant in a conductor; but, with the rapid oscillations used in these experiments, it is possible that their direct effect is to render the attenuated gas luminous, and the glow itself is called a discharge or a current. On the other hand, that a true discharge or current is set up was conclusively proved by providing several long lengths of tube, which, while forming part of the closed secondary circuit of the transformer, were not subject to the magnetic field, and yet exhibited a glow precisely similar to that which was seen in the coils directly influenced by the primary coils.

In view of the well-known dark space in ordinary vacuum tubes, and of the fact that in a stratified discharge the portions between the striæ are sometimes entirely devoid of glow, and, further, of the observations of DE LA RUE and MÜLLER, who suspect the existence of invisible striæ even in the dark discharge, since they detected a development of heat in the middle of a tube in which there was no illumination except at the terminals, it is not safe to say that when no luminous band is to be seen in one of these closed circuits there is no discharge, and still less safe is it to account for the non-appearance by supposing the velocity of the discharge to be that of light. Prof. THOMSON, in reply to the remarks of Dr. LODGE, observed that although a firm believer in MAXWELL'S theory, he did "not believe that everything went with the velocity of light." It is rather a fault of Maxwellians that they try to prove every velocity to be the same as that of light in air, forgetting how this velocity varies in different substances and for different kinds of light.

OBITUARY.

EDMOND BECQUEREL.

In the person of M. Edmond Becquerel there passes away a notable figure from the ranks of Continental electricians. Born at Paris, March 24, 1820, he had just completed his seventy-first year; the greater part of this long life having been spent in active scientific work. His father, the veteran Antoine César Becquerel, the friend of Davy, Faraday, de la Rive, Ampère, Arago, and all the notabilities of the former generation, died at the age of ninety, in 1878. From 1823 to 1863 he had worked incessantly at electro-chemistry, atmospheric electricity, and kindred problems; and in many of the later

Digitized by Google

of these researches his son Edmond was associated with him. We find the son, brought up amongst scientific associations, early developing a passion for research. When but twenty years of age he presented to the Academy of Sciences at Paris a thesis "On Some Chemical and Electrical Effects produced under the influence of Solar Light. In the preceding year, 1839, he had joined with his father and with the Academician Biot in the preparation of a memoir on the phosphoresence resulting from the light of electric discharges. This memoir was printed in the archives of the Museum of Natural History in Paris, where the elder Becquerel held the Professorship of Physics, to which many years later the younger Becquerel succeeded. He continued his father's researches on electro-chemical phenomena, and made, in 1856, a very complete study of the electromotive force and internal resistance of primary batteries. In 1853 he attacked the difficult problem of the transmission of electricity through gases at high temperatures. In 1861 he made a study of the conductivity of liquids in capillary tubes, and showed that by this means a rheostat might be constructed having many hundreds of thousands of times as much resistance as the kilometre of telegraph wire then used as a standard of comparison. At one time he paid much attention to the subject of magnetism, and conducted a series of researches on the diamagnetic properties of bodies, using for that purpose an electro-magnet of a size which at that date—1846—had scarcely been equalled in power. He also made an examination of the distribution of magnetism in very attenuated wires of steel. In conjunction with his father he was the author of several important treatises. In 1847 they published a work on the elements of terrestial physics and meteorology. This was followed in 1855 by a treatise on electricity, the third volume of which, on magnetism and electro-magnetism, was mainly by Edmond Becquerel; the first being on statical electricity and general phenomena, and the second on electro-chemistry. In 1858 they brought out a résumé of the history of electricity and magnetism, a work conspicuously illustrative of the strong, as well as of the weak, points in French historiography.

But Becquerel's work was not confined by any means to electrical subjects; it was in another department of physics that his life's work was mainly accomplished. He devoted himself with all the eagerness of his nature to the recently-discovered chemical effects of light; and for many years he continued to pour forth memoirs of his experimental researches upon this and kindred branches of optics. It was he who discovered that all the colours of the spectrum can be impressed upon a photographic film of chloride of silver, provided it has been already faintly illuminated by an ultra-violet ray to start the sensitive state. It was he who discovered the de-sensitising effect of the infra-red (or "heat") rays, and by means of this phenomenon proved the existence of absorption lines or bands in this invisible region of the spectrum of solar light. He made the subject of phosphorescence peculiarly his own. He devised the "phosphoroscope," wherewith to study phosphorescent bodies and the duration of the period during which they emit their light. In 1867, being then Professor of Physics at the Conservatoire of Arts and Industries, he published two splendid volumes entitled: "Light, its Causes, and its Effects." In this work he collected all that was known on the subject of the emission and production of light, on its relations to heat and electricity, on its analysis by the prism, and on the phenomena of fluorescence and phosphorescence. He made a special study of the production of phosphorescence by exposure to light, and of the remarkable phosphorescent qualities of the sulphides of the alkaline earths, of which the modern "luminous paint" is the outcome. This work remains his masterpiece, and will long be consulted as the standard treatise on these subjects.

During the last fifteen years, as age told upon him, he relinquished active research work; and he was latterly surrounded by men of a younger generation, who were absorbed in newer problems, in which he had no part. His place is, however, worthily filled by his son M. Henri Becquerel, who has already made his mark in researches both in optics and in magnetism, and who carries forward the honourable traditions of scientific devotion with which the names of his father and grandfather are associated.

ON SOME EFFECTS OF ALTERNATING-CURRENT FLOW IN CIRCUITS HAVING CAPACITY AND SELF-INDUCTION.*

BY DR. J. A. FLEMING.

(Continued from page 49.)

15. In the course of various experiments during the laying of the cable, it became evident that a conductor having so considerable an electrostatic capacity behaved in a curious manner under some circumstances when long lengths were connected up to a transformer. This behaviour has been much misunderstood, and much misdescribed. Remarkable phrases have been coined with reference to it, such as "the piling up of the volts," or "packing up of the volts," which are not very lucid descriptions of what really does occur. Ingenious theories have been constructed, also, to account for phenomena which do not exist. Briefly stated, it appears to be as follows:—When an insulated and sufficient length of the cable has its inner and outer members connected to the terminals either of a transformer or of an alternator having an armature of sufficient inductance, it is observed that under these conditions the potential difference between the inner and outer members, measured anywhere along the length of the cable, is generally greater than would be the potential difference of the terminals of that alternator or transformer if the cable were very short, or not present at all. This seems to hold good also when the far ends of the inner and outer members are connected together through a not very small resistance, such as a row of incandescent lamps in series, or a high-resistance voltmeter, or transformer lightly loaded. The cable acts in all apparently as one single condenser would do, and in no case, as far as is known, is there evidence of a continuous rise of pressure along the trunk mains themselves. The pressure at the London end is not found to be greater than at the Deptford end. The condenser effect is increased apparently by increase of length of the main, at least within observed limits, and in all cases the main acts as if it were a condenser bridged across between two parallel mains without capacity. When current flows into the cable there is a flux across the dielectric from inner to outer member which constitutes the *condenser current* of the mains, and the outflowing current is in general less in magnitude than the inflowing current, although not always necessarily so. The current flowing out at the London end may be called the *work current*. There is a difference in phase between the work current and the condenser current. The ingoing current is the resultant of the work and condenser current.

16. In order to examine the phenomena of these trunk mains more closely, some experiments were made on one length of nearly 12 miles of the cable by joining the conductors of two trunk mains in London, and having both ends of this gigantic loop of concentric cable at our disposal in the Deptford station. These experiments were arranged by Mr. Ferranti to give Mr. Preece, Major Cardew, and me the opportunity of obtaining measurements of these condenser effects in the Ferranti trunk mains. The experiments were made on Friday, January 9, 1891, at Deptford, and Mr. Ferranti, Mr. Sparks, Mr. D'Alton, Mr. McLean, and the assistant engineers took part in carrying out these measurements. The arrangements were made as follows (see Fig. 10):—One of the 1,200 H.P. dynamos (No. 2) was set apart for the purpose, and excited so as to supply current at about 2,500 volts or so. The current from this dynamo was led through the primaries of two 150 H.P. transformers joined in parallel, and which raised the pressure from 2,500 to 10,000 volts. At this pressure a current from the secondaries was sent into the concentric cable at Deptford, thence to the sub-station in Trafalgar-square in London by one main, and back to Deptford on the other trunk main. This total distance is 20,224 yards, or 11·49 statute miles. Arriving back at Deptford, the current was again reduced from 10,000 to 2,500 volts, and the energy taken up in water resistance in a water tank at the latter pressure. The pressure at different parts of the system was measured by Cardew voltmeters, the high pressures being reduced by 100: 1 pilot transformers. The currents were measured by Evershed ammeters. The current and pressure were measured at four places—viz., at the terminals of the dynamo, at the beginning or entrance of the trunk main, at the end of the trunk main, and, after reduction, at the tank. Observers stationed at these different instruments took simultaneous observations at a signal given by the sound of a whistle, and in this way the simultaneous values of the pressure and current were obtained at these four places. The transformers used for raising and lowering the pressure were the 150 H.P. size, having on the primary side 1,120 turns of wire, of resistance 3·5 ohms, and on the secondary side 280 turns of wire, having a resistance of ·2442 ohms. Hence these transformers were 4 : 1 transformers. There were, in addition, a pair of pilot transformers, which had a change ratio of

* Paper read May 7, 1891, before the Institution of Electrical Engineers.

Digitized by Google

100 : 1, and which reduced from 10,000 to 100 volts for voltmeter purposes. The observations consisted in exciting the dynamo to various voltages, and observing the current and pressure at the four places named, whilst different loads were placed on the system by taking up more or less current in the tank.

17. From a large number of observations the following are selected as showing the general results obtained, and are set forth in Table I. The first column gives a number for each experiment. The second and third give the pressure and current at the dynamo terminals. The fourth column is a series of numbers which are four times those in the second column, and are the pressures to which the 1 : 4 step-up transformers at the home end would raise the dynamo pressure if the cable were absent. The fifth and sixth columns give the pressure and current at the home, or dynamo, end of the trunk main, and it will be seen that in every case this observed pressure is greater than four times the pressure at the dynamo terminals. The seventh and eighth columns give the pressure and current at the far end of the trunk main, and it will be seen that in every case the current flowing out of the main is less than that going into it. Columns X. and XI. give the pressure and current after reduction by the step-down transformers, at which pressure the energy was taken up on water resistance in a tank. Column IX. gives the pressure on the primary, or cable, side of the 4 : 1 step-down transformers, which would be necessary to give the pressure observed at the tank if the cable were not present.

18. We have then to see how these observed values agree with theory. It must be, however, stated that these numbers and values so observed are not minutely accurate. Owing to the fact that the speed of the dynamo varied slightly, and to the fact that the Cardew voltmeters used were set vertical, and not horizontal, some degree of inaccuracy exists in the readings of current and pressure, but the figures are perhaps sufficient to test the general agreement of fact with theory.

We note, first, that in the experiments at full load, when 118 amperes was being taken up in the resistance, the load on the transformers was about 340 H.P., and hence the two 150 H.P. transformers at each end joined in parallel were slightly over-

loaded. Under these circumstances, the inductance of the transformers at the step-up end is reduced practically to a very small value, and we may consider that the actual current of 30 amperes or so flowing in the cable can be considered to be the resultant of two superimposed currents differing about 90 degrees in phase from one another. There is, first, the *work* current of 26·5 amperes in Experiment I. which is flowing out of the cable, and which is practically in synchronism with the impressed electromotive force in the secondary circuit of the step-up transformers. Then there is the *condenser* current of the cable considered as one single condenser, which will be 90 degrees in advance in phase of the impressed electromotive force creating this charge. Hence the values of the ingoing currents given in column VI. are the resultants of the outgoing currents given in column VIII., and the condenser current of the cable, which is in quadrature with the last. Hence the magnitude of the condenser current must be the square root of the difference of the squares of the currents given in columns VI. and VIII., which may be called respectively the *resultant current* and the *work current*.

Taking the first six experiments in Table I., we calculate from them the square root of the difference of the squares of the currents in columns VI. and VIII. of Table I., and write them as in Table II. below.

Table II.

Unfortunately, the speeds of the dynamo were not taken at each observation; but the normal frequency of the current from these dynamos is 67, and in these experiments the dynamo speeds were marked as rather below the normal. If $n=67$, $2\pi n=p=421$. It is probable that the value of p was not greater than 400 in these experiments. We have seen (equation 2, *ante*) that if v is the instantaneous potential difference of the condenser terminals, and i the current flowing into it at any instant, $i=C\frac{dv}{dt}$. Hence, on the assumption of a simple periodic variation of the current, we may write p for $\frac{d}{dt}$, and put as the value of the square root of the mean square of the condenser current, I, the expression,

$$I = p C V,$$

where C is the capacity, and V is the potential difference of the terminals of the condenser as read by an electrostatic or Cardew voltmeter. It then follows that the capacity of the cable is determinable from the values of the condenser current, I, the pressure, V, as read at the step-up end, and from the known value of p.

We may examine how far the capacity value so deduced agrees with measurement.

We tabulate in columns the values of the condenser currents, I, found from Table II., and set against these the mean potential difference of the inner and outer members of the cable as the mean potential difference of the surfaces of the condenser. Calling these last values V, we then calculate the capacity, C, in microfarads from the formula,

$$C=\frac{I}{pV}\times 10^6,$$

on the assumption that $p = 400$. These results are set down in Table III. The values of the potential, V, are the means of the pressures given in columns V. and VII. of Table I. as the pressures at the step-up and step-down end of the trunk main.

Table III.

12·2	9,005	3·4
14·4	9,935	3·6
15·5	10,210	3·8
12·2	9,020	3·4
14·4	9,635	3·7
13·1	9,440	3·5

The mean electrostatic capacity of the 11·5 statute miles of the cable in use is, therefore, about 3·6 microfarads, as deduced from these experiments. On the day following these experiments the electrostatic capacity was measured at Deptford by Mr. H. R. Kempe, using a microfarad standard and a battery of about 18 Daniell cells, and taking galvanometer throw observations in the usual way. Mr. Kempe found the capacity under these circumstances of the respective mains to be about 1·98 and 2·02 microfarads, or in all about four microfarads. Accordingly, we see that the capacity, as deduced from the mean calculated condenser currents and the observed pressures at the ends of the mains, comes out a little low compared with the measured steady value; but the speeds and pressures were hardly observed with sufficient accuracy to make a closer agreement very likely, and the condenser current values are probably affected by some errors. It may be observed that the effect of a small but definite inductance in the fine-wire circuit of the transformers at the step-up end existing unannulled at full load would be to lower the condenser currents, and hence to lower the calculated capacity. I think it is pretty clear that what may be called the normal condenser current of the 11·5 statute miles of the trunk mains is about 14 or 16 amperes under a working pressure of 10,000 volts at the step-up end of the main, and at a frequency of about 67 for the circuit. This is what is generally observed.

On one occasion, when the writer was engaged with Mr. Ferranti in testing the trunk mains, we had a similar arrangement of the system to that above described—viz., a length of 11·5 statute miles of trunk main looped in London through two step-down and step-up transformers in parallel, and a similar set of transformers at Deptford.

Two 100 c.p. lamps were put on the far end of the system at Deptford, just to give indication of a current flowing through the system; otherwise there was no load. When the dynamos were excited so as to give 2,500 volts on the primary side of the step-up transformers, and this raised to 10,000 volts in the mains, we found a current of about 64 amperes going out of the dynamo at 2,500 volts. This would correspond to 16 amperes or so in the trunk mains. The actual working current at this time was merely the magnetising current of the step-down transformers and the normal current required for the lamps. Hence this experiment agreed in showing that the normal condenser current of the trunk mains at 10,000 volts pressure and a frequency of 67 is about 1·4 amperes per mile run of the cable.

19. Let us next examine how far the observations taken with no load on the secondaries of the step-down transformers agrees with the foregoing. In this case we restrict our view to the last eight observations recorded on Table I. The numbers in column IV. give us at once the condenser current of the cable, because there is no sensible current flowing out of the cable except the negligible magnetising current of the transformers.

Table IV.

Condenser Current, I, in Amperes.	Mean Potential Difference of Condenser Surfaces of the Cable, in Volts.	Calculated Capacity for the Whole Length, in Microfarads.
11	9,885	2·8
11	9,985	2·8
10	7,295	3·4
5	5,200	2·4
9	5,500	4·1
9	5,900	3·8
10	7,920	3·1
12	9,395	3·2

The variation in the values of the capacity shows that the measurements of the condenser currents are probably affected by considerable errors; and this is likely, seeing that the ammeters on the end of the trunk main would not read with sufficient accuracy to detect a difference of one or two amperes at these low readings. Hence all we can say is, that the mean capacity of the cable as deduced from the observations at no load—viz., 3·3 microfarads—is not extravagantly different from that obtained by observations at full load.

If we take one of the observations at half load—say No. 10 in Table I.—we arrive at the same result. For the ingoing and outgoing currents in the trunk main are then 22 and 17 amperes, and the difference of their squares is 14, which is probably nearly the condenser current in this case; and the mean potential difference of the surfaces of the cable is 10,560 volts; and hence, as before, the capacity comes out 3·3 microfarads for the whole length. Hence all the observations agree in giving a capacity of from 3·3 to 3·6 microfarads for the total cable in use. It may well be questioned whether for this paraffined-paper dielectric the capacity as

Digitized by Google

determined by a prolonged charge and discharge gives a value which is correctly expressive of the true working capacity of the cable under rapid alternations of charge. It must be remembered that paraffined paper presents usually a considerable absorption effect, and the value of 4 microfarads for the 11·5 miles, obtained by the usual ballistic galvanometer method, may be, and perhaps is, a value which is higher than that which correctly expresses the true working capacity of the cable under rapidly reversed electric stresses. It is important to have this point investigated for the dielectrics in use in the manufacture of types of concentric cables now employed.

20. Passing to the examination of other points indicated by the observations in Table I., we see that the mean potential difference of the two conductors of the cable is always greater than four times the dynamo terminal pressure as given in column IV. That is to say, these figures show that the pressure in the trunk main at the dynamo end is always greater than would be the pressure at the terminals of the step-up transformers if the trunk mains were disconnected. This may be said to be the fundamental phenomena which has been much dis-described and misunderstood. The values of the pressures as read at the dynamo terminals and at the two ends of the trunk mains show that whenever the system is loaded, and there is a fairly heavy load, there is a fall of pressure down the cable, as there should be; although the actual figures seem to show that this fall of pressure is not quite equal in value to the product of the values of the true resistance of the cable and the current flowing through it. Those cases in which the figures in Table I. seem to show a rise of pressure along the main cannot be accepted as representing the actual facts. When the cable is relieved of all working current, and only traversed by a condenser current, the figures show that the cable is either all at one pressure all along, or else that there may be a slight rise from the step-up end to the step-down end of the cable. I think, however, that there is no good evidence of this rise of pressure from end to end of the cable when not loaded with external load. The chief fact is that, whereas the step-up transformers would, if existing alone, raise the dynamo pressure fourfold, we find that when the cable is heavily loaded the mean potential difference of the conductors exceeds four times the dynamo terminal pressure by something like 5 per cent.; and, when the external load is removed, that excess pressure more nearly amounts to about 10 or 15 per cent.

The general fact is quite in accordance with the foregoing theory. When the step-up transformers are heavily loaded, the inductance of their secondary circuits is practically annulled or very much reduced; when they are lightly loaded, it is at once increased. We have seen, in discussing the clock-diagram of electromotive forces as applied to this condenser problem, that the increase in pressure which takes place is always an evidence of the presence of inductance in the charging circuit, and that this rise of pressure will augment with increase of inductance in the line or in the step-up transformer. We are unable to test how far the general rise of pressure is in accordance with the foregoing theory, because we have no means of measuring the true mean inductance of the secondary, or high-pressure, side of the step-up transformers. The presence of capacity in the line always keeps down the inductance of the transformer, because it compels a rather large current to flow into it from the dynamo, even when the work current flowing out of the cable is zero, or nothing more than the magnetising current of the step-down transformers.

21. In the foregoing paragraphs no attempt has been made to enter into a discussion of the physical *modus operandi* of these condenser effects. We can easily construct, as has been frequently done, mechanical analogies, in which the elastic yielding of a spring and the inertia of a heavy body take the place of the capacity and inductance in the electric system. It is possible, however, to overrate the value of this mechanical parallel. It is probable that the actual physical operations taking place to produce these electrical effects are not adequately represented by a mechanical simile in which the inertia-like aspect of self-induction is exclusively regarded, although, of course, such mental representations have their use. Too much hypothesis is often as bad as too little in seeking to connect together observed facts and fundamental principles. We may regard a condenser, when subjected to periodic currents, as a non-dissipative impedance, if the term may be allowed, having also a negative self-induction. A condenser allows a flux of electricity to take place backwards and forwards through its dielectric, and, as far as alternating currents are concerned, it may be said to have a conductivity for electricity.

A condenser of capacity C, when traversed by periodic condenser currents of frequency n, acts in any circuit as equivalent to an impedance of magnitude $\frac{1}{C\,p}$. It also acts as if it had a negative inductance equal to $\frac{1}{C\,p^2}$, p, as usual, standing for $2\pi n$. By a negative inductance $\frac{1}{C\,p^2}$ must be understood a power of nullifying positive inductance in a conductor in series with the condenser numerically to the amount of $\frac{1}{C\,p^2}$ henrys. Suppose, then, that a condenser of capacity C is placed in series with an inductive resistance L and resistance R, and a periodic potential difference equal to V_0 permitted to act on the two in series. The resultant inductance of the whole circuit is $L - \frac{1}{C\,p^2}$, and the resultant impedance is

$$\sqrt{R^2+\left(L-\frac{1}{C\,p^2}\right)^2 p^2}.$$

Hence the current through the condenser is equal to

$$\frac{V_0}{\sqrt{R^2+\left(L-\frac{1}{C\,p^2}\right)^2 p^2}}.$$

If the potential difference of the two sides of the condenser is called V_1, and the equivalent impedance of the condenser is $\frac{1}{C\,p}$, we may consider that the value of V_1 is obtained by taking the product of this so-called impedance of the condenser, $\frac{1}{C\,p}$, and the value of the current flowing through it. Hence we have,

$$V_1 = \frac{V_0}{\sqrt{R^2+\left(L-\frac{1}{C\,p^2}\right)^2 p^2}} \frac{1}{C\,p};$$

but this is the same expression as that deduced before, for the ratio of V_1 and V_0. This is not to be considered as a demonstration of the equation, but only as showing how it may be regarded as being built up on the assumption that a condenser behaves towards alternating currents as an impedance causing fall of potential in a current passing through it, and capable of nullifying inductance in a circuit connected in series with it; and that such a view leads to an equation from which it is immediately seen that under some conditions V_1 must be greater than V_0.

(To be continued.)

SOME RESEARCHES IN ELECTRO-MAGNETIC INDUCTION.*

BY E. B. VIGNOLES.

(Concluded from page 51.)

I have entered into a lengthy and detailed description of the method employed, as it is novel, and presents very great advantages. I have thought it better to be too precise rather than not precise enough; for it is generally my experience that it is exactly the information you wish most to have which is omitted. For instance, in Dr. Hopkinson's classic Paper, the actual observations from which the curves are taken are not given, and from the scale of these the lower parts are difficult to trace.

In the following tables I give you the actual figures of some typical results.

The apparent increase in permeability is accounted for exactly by supposing the scale to have no permeability. Its removal decreases the area, and therefore increases the apparent **B**.

Note in the second curve, No. IIIa, the displacement of the curve with regard to the zero of magnetising force. We have not been able hitherto to account for this phenomenon satisfactorily. We have found it in several curves, the displacement being in some cases very large. It is perhaps due to a bias in the iron produced by a previous very high magnetising force in the direction of displacement.

This curve may be folded back to form the falling curve, as we have found that taking the falling curve by "breaking" methods gives too small an area, owing to causes which hardly come within the scope of this Paper.

I have given the falling curves obtained by carrying the iron through the cycle to the required point on the downward curve and then breaking P_2; but since taking them we have discovered the reason of their "humpbacked" appearance. In nearly every case, the falling curve comes down more perpendicularly than the rising curve, and for getting the hysteresis area more accurately it is best to fold over the rising curve. The iron cannot know which way round it is.

These curves only give an idea of the behaviour of cast iron. This material is very variable in its magnetic properties. Other specimens have given higher permeability.

* Paper read before the Old Students Association, May 13th, 1891.

3	17·3	11·2	7	210	19·0
4	48·8	15·2	8	288	19·9

I will now give you the result of a test of a specimen of mild cast steel, from Langley Mills, Nottingham. Note that for large magnetising forces its permeability is nearly as great as wrought iron. The observations are by reversal method, as the hysteresis area was not required. The steel was not annealed.

Curve VI. shows the result of introducing air gaps amounting to $\frac{4}{1000}$ inch in a Lowmoor iron ring of 1·13 sq. cm. area, and 31·4 cm. long. It was obtained (the A curve) from a continuous ring, which was then sawn through, and the gap refilled by a piece of the same material, grain in the same direction. Thus treated the curve fell to B, a difference even at large induction densities of 5 per cent. or so.

Curve VII. exhibits in a comprehensive manner the results o the tests, taking average permeability, and as far as dynamos are concerned, these curves give all the information necessary.

The above curves embody practically every material which we have tested.

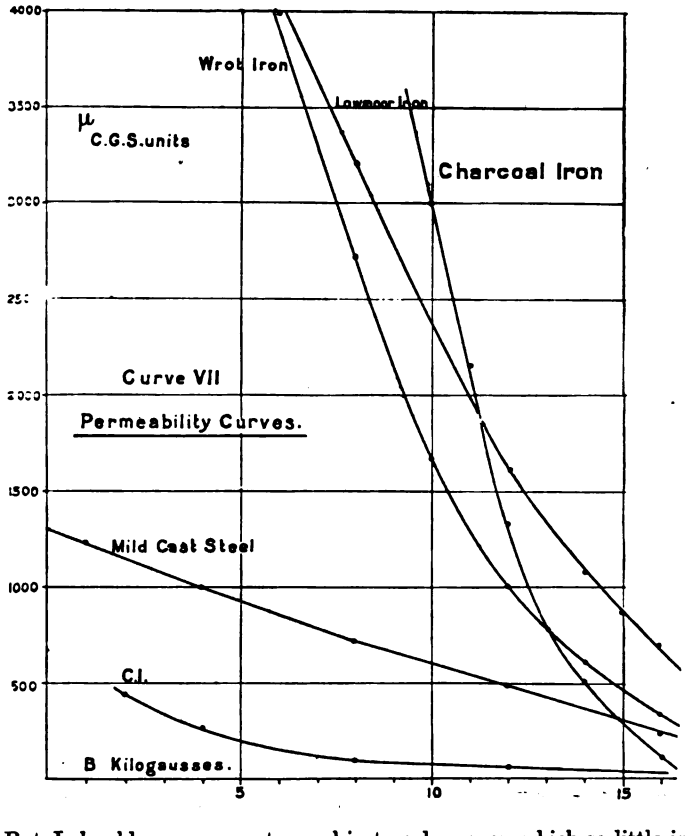
I could say much as to interesting side issues which have cropped up in the course of the research, but I have thought it best to keep strictly within the lines laid down at the commencement—a description of our method and the results obtained by it.

Even as I write this, I see the bearing of much of our work upon such vexed questions as the supposed "Mordey effect" (the decrease of hysteresis at full load), viscous hysteresis, and so on.



But I should open so vast a subject and one on which so little is known, if I were to be led off to these subjects, that I think these questions must be reserved, I hope for a future Paper.

At the same time I cannot help stating here, that some of the points brought out by these researches seem to us to have vital bearing on the subject of transformers, and also to a certain though less extent on that of dynamo armatures; and these points it will now be our business to further investigate.

[A full report of the discussion on this paper will appear in our next issue.]

ELECTRIC LIGHTING AT GLASGOW.

A Special Sub-Committee of the Glasgow Corporation has for some time past been engaged in considering what steps should be taken by the Municipality with regard to the carrying out of the powers entrusted to it under its electric lighting Provisional Order of last year. As already reported in these columns, the Sub-Committee, after receiving reports from Sir William Thomson, Mr. R. E. Crompton, and Prof. Jamieson, has recommended the Corporation to spend some £60,000 on an electric lighting scheme. We print this week the reports in question.

Sir William Thomson's Report.

1. For lighting the compulsory district, marked in the plan which accompanied your letter, the low-tension direct current system is, in my opinion, for many reasons decidedly preferable to the high-tension alternate current system with transformers, and is the system which ought to be adopted.

2. The method of distribution by feeders and distributing mains, patented by Edison for this country and America in 1882, ought to be adopted. It is adopted in the Kensington and Knightsbridge Lighting, and in the Westminster Electric Supply. I do not know whether any claim for patent right has been made upon them by Edison or his agents. The method, which is of great importance, was certainly described quite clearly by Edison in his patents. It seems probable that the question will be raised by Edison's representatives in this country when the result of litigation regarding it in the United States is known. I gave evidence in the American case, at the request of the Edison Company, and I think it right to point out to the Glasgow Corporation that there is at all events a possibility of a claim for royalty for the use of the system having to be met.

3. The supply station ought to be as near as may be to the district to be lighted. The nearer the better for good economy.

4. A moderate amount of storage battery should be provided, about enough, perhaps, to serve well for several hours at about 15 per cent. of the maximum ordinary rate of consumption. This would allow all the engines of the central station to be stopped, as a rule, every day from 4 a.m. till 8 a.m., and for a longer time, at all events in summer, if desired. The Howell-Crompton type is the best hitherto produced for the purpose of town lighting from central stations, because it is especially adapted to work with moderately good economy, and without damage to itself, for about one hour or somewhat more at an abnormally high rate of action, and so to meet a sudden demand, such as that entailed by a fog coming on suddenly, and to give fairly well the requisite supply of light until steam can be got up and the engines working from the central station at full power.

5. If the lighting was to be confined to the compulsory district alone, and a central station is provided, either within it or close to its boundary, the two-wire system would be preferable to the somewhat less simple three-wire system. But as large extensions to different parts of the town will no doubt be made, before long it is to be hoped, it would, I think, be right to begin at once with the three-wire system, with about 250 volts between the + and − mains, so as to be able to provide 110 volts for the houses.

6. In choosing a site for a central station, it is of great importance that there should be facilities, not only for carrying in coals but for carting away ashes, and as economically as possible, and with as little as possible of annoyance to the public.

Prof. Jamieson's Report. (Abstract).

The "*Direct Supply Low-Pressure System*" is both good and economical. But a slight variation in the speed of the engines instantly causes a corresponding variation in the light of the consumers' lamps. A complete stoppage, or even partial break-down, of the boilers or engines, or of the dynamos, &c., means a corresponding obliteration of the consumers' lights. The companies have to keep in readiness spare plant, so that it may be started at a moment's notice to replace any faulty corresponding portions. The mere act of putting this spare plant into gear, or even the addition or subtraction of an engine or dynamo, to those already in circuit is, as a rule, rendered clearly visible by a fluctuation of the light supplied to the public.

Combination of Dynamos with Storage Cells.—The liability to alteration or extinction of the lights is as far as possible at present avoided by the employment of storage cells. There are two practical well-tried methods. One of these is adopted at Kensington, and the other at Chelsea. Both of these methods employ tubulous boilers, generating steam at about 200lb. pressure on the square inch, to supply high-speed vertical compound engines, coupled direct to dynamos at the central station. Mr. Crompton conveys the outgoing current by means of the three-wire system of bare copper mains arranged in concrete culverts, to sub-stations where storage cells are kept. During the hours of small demand for current these batteries supply current at the required voltage.

The Electric Installation and Maintenance Company convey their current from their central stations at about 1,700 volts through underground mains to *one-half* of their sets of batteries at sub-stations in series. When this one-half has been fully charged, then the other half is automatically brought into circuit with the dynamos at the central station, whilst the fully charged set is automatically placed in direct circuit with the consumers' lamps. Only one attendant is employed at one time to periodically visit the sub-stations three or four times a day in order to see that things are going all right. But these automatic devices cost, at least, 10 per cent. of the whole outfit for the sub-stations, and consequently it is a matter for your consideration whether the advantages gained by the use of such devices and the disadvantages of their up-keep, compensate for the advantages gained by the more direct supply method employed by Mr. Crompton.

In the "*High-Pressure Alternate Current Transformer System*" of Mr. S. Z. de Ferranti, using 10,000 H.P. engines and an electrical pressure of 10,000 volts, there are immense possibilities as to the economical supply of electrical energy from a distant source of power. But this system, at such a high pressure, has scarcely had a sufficiently lengthy trial to warrant your recommending its adoption at present in Glasgow. Yet you have had working in the very centre of Glasgow for the last two years a central station, arranged upon the Ferranti system, with a lower voltage, viz., 2,400 volts, which has proved successful with overhead mains. These overhead mains will have to be replaced within two years by underground

Digitized by Google

ones, by order of the Board of Trade. For high-pressure currents I have not met with any mains better than those devised by Mr. Ferranti.

Underground Electric Lighting and Power-Distributing Mains.—I have laid before you specimens of mains with prices. After very careful examination of the advantages and disadvantges of each kind, I am led to the conclusion that, for straight runs underneath the pavements of the streets, and for low-pressure supply, Crompton's concrete culverts, with bare insulated copper strip mains, are both the cheapest and the most elastic for extension. Where corners, crossings, and awkward bends have to be made then Siemens, or the India-rubber and Gutta-percha Company's best vulcanised india-rubber cables, drawn through pipes, or Callender's cables, may be used, as is found most convenient for each case.

Mr. R. E. Crompton's Report.

In accordance with your instructions I send you my report on electric lighting. These instructions were that I should prepare a scheme for lighting, by electricity, the streets in the compulsory, or what I hereafter call the central area.

Acting in strict accordance with your instructions, 1 first prepared a scheme for furnishing 5,000 16-candle lamps, lighted simultaneously in the central area from Partick. I prepared a second one for lighting the same area from Dalmarnock, but, as in both cases I find that the cost of the mains connecting the generating stations with the area was so great as to be disproportionate to the rest of the plant, I have prepared four other schemes with a view to ascertaining how far this cost of the mains can be reduced.

The object of working out these six schemes was to enable me to lay before you their comparative advantages and disadvantages, the capital expenditure likely to be incurred on each, and the cost of production of the electric light by each of the six schemes at varying scales of output. I have attached three sheets, marked A, B, and C, giving the result of my calculations. Sheet A is a tabular statement of capital expenditure. B is a tabular statement of what I call engine-room expenses—that is to say, the cost of working your plant within the engine-room. This portion of the cost, when calculated per unit, being pretty constant within wide limits of the scale of production; and C, the total cost of production, showing; 1st, the general charges; 2nd, the percentage charges for repairs, renewals, and interest on capital, all of which may be called fixed or standing charges, and which, when added to the engine-room expenses, give the total annual cost of production for any given output. I work this out in the case of the three partial schemes for 200,000 and 400,000 units per annum, and in the case of the three larger schemes, 200,000, 400,000, and 800,000 units per annum. In every case I have reduced the total cost of production into pence per net units sold, and these figures are entered in red, and are an accurate measure of the comparative merits of the six schemes.

In the first five of these schemes I have used the method of distribution that was applied by me successfully at Vienna, and is known as the five-wire system. I use continuous currents at 450 volts in combination with accumulators situated at several sub-stations. The pressure 450 volts is defined in the Board of Trade rules as a low pressure system, and is perfectly safe. This pressure extends only from the dynamo station up to the terminals of the accumulators in the sub-stations, which are led away to the houses at half this pressure and in the houses themselves at a quarter this pressure.

In Scheme No. 6 I do not even propose to use the 450 volts but the ordinary three-wire system that I am using in Kensington and our other London stations, the pressure in the charging mains being 240 volts, and in the houses 100 volts. In addition to the three important sheets, A, B, and C, I enclose sheets E, F, G, and H, which give in very full detail the method of working out the cost of the low-pressure network of conductors which distribute the electrical energy from the sub-stations to the consumers' houses. I may here remark that the cost of this portion of the system of electrical conductors, which it is convenient to call the network, is common to all systems of electrical supply, whether the systems be high or low pressure, as later experience in the use of the high pressure alternating current with transformers has shown that in future it is not safe or advisable to put the transformers in the consumers' houses, and that these high pressure systems must distribute from transformer sub-stations by means of a low pressure network.

Although my instructions related more particularly to Scheme 1, viz., that of supplying 5,000 16-candle lamps in the central area from Partick, yet as the result of my calculations show us very definitely that Scheme 6 is so greatly superior to the others that I think it will be most convenient for me to describe in full detail Scheme 6, and explain in what important points the other schemes differ from it.

Scheme 6.—Generating Central Station.—The Corporation to purchase land or pay ground rent for a site in a central position. The area required is about 550 square yards. I have allowed £5,000 as the cost of a substantial building of three floors, with a chimney of 130ft. high. On the ground floor will be placed a range of six boilers of the dry back marine type, each about 200 H.P.—that is to say, having 1,000 square feet of heating surface. On the same floor, arranged parallel to the boilers, I place on substantial foundations a row of five steam dynamos, each of 200 H.P. In addition to these I supply two small steam dynamos, each of 90 H.P. On the first floor, extending over the whole of the engine and boiler room, would be space for the home batteries of accumulators, and for stores and workshop. Over this can be placed rooms for the resident engineer in charge, and the offices.

Sub-Stations.—In Scheme 6 I only propose to put down one sub-station, to contain two batteries of accumulators. The space for these two batteries being small, and there being no machinery in motion to create a nuisance, it is usually an easy matter to find such a station in the "back" land, even close to a better class of property. One floor, 20ft. wide by 50ft. long, is ample for the purpose, provided it is strong enough to carry the weight, and is fairly well lighted and ventilated. The accumulators which I propose to employ were originally designed by Mr. Howell, of Llanelly, and have since been improved by myself. Four years' experience of their use in London have shown that the cost of up-keep of this class of accumulator is far less than had hitherto been supposed to be the case. Up to the present, the cost of repairs and renewals has not reached 10 per cent. of their first cost; but, in view of the possibility of heavy repairs to the plates being needed after six or seven years, I am in the habit, in all my calculations, of allowing a sum of 14½ per cent. per annum as the cost of the up-keep of these accumulators and their stands, and I believe this to be a perfectly safe and outside figure.

Distribution Plant.—If the local circumstances in Glasgow will admit of the use of the system of bare copper conductors strained in culverts, which I have applied with such success in London, I should strongly recommend it. In case, however, the local conditions at Glasgow are such that these culvert mains cannot be employed, I can use two other alternative methods of laying the conductors; one, that of drawing insulated cables into pipes laid in the streets; and the other that of using the patent bitumen trough system, invented and successfully employed by Messrs. Callender in Liverpool, Birmingham, and other towns.

My estimates are worked out on the supposition that three-quarters of the laying will be carried out on the culvert system, and one quarter on either the pipe or Callender system. The prices on which the cost of the culvert system has been worked out are obtained from actual experience in London, but we find that the cost in other towns, such as Northampton, is considerably less than in London, and it is possible that this may be the case in Glasgow. Whichever of the three systems, or if a combination of the three systems, is employed, in every case I propose to supply a large number of service boxes, or openings in the streets, at which ready access can be given to the conductors for the purpose of making the connections to the adjoining houses, or for repairing them, or withdrawing them and replacing them by others, in case this should be found necessary. All this can be done without further disturbance of the surface of the streets. I am strongly of opinion that such a provision is a necessary one in the case of electric lighting distribution plant, as it is impossible for anyone to say, with any degree of certainty, what number of houses facing the mains will eventually take the light. Actual experience in London has shown us that the attachment of the houses to the mains is a gradual process, and if it were necessary to open up the streets every time this is desired to be done, it would be an intolerable nuisance to the traffic, as well as spoiling the surface of the street. By my culvert system, combined with the pipe system above mentioned, I have succeeded in entirely avoiding this nuisance in London. Every alteration, or repair, or attachment that has been necessary during the four years the underground mains have been in use in the Kensington and Knightsbridge district, has been carried on at night without any disturbance whatever to the traffic of the streets.

Engine-room Expenses.—This portion of the cost of production can be estimated by us engineers with great certainty. After the consumption has once passed a certain comparatively low limit, the fuel, water, and petty stores used is almost directly proportional to the output in electrical units. The cost, however, of the labour item is greatly reduced as the output is increased, and will, I believe, be reduced to more than I have shown it in my table. I have assumed coke at Dalmarnock, 2s. 6d., per ton; Partick, 4s. 3d.; and at the central station, 5s. The cost of water at 4d. per 1,000 gallons is also assumed, but you will see that a slight variation in these two assumed prices will not materially affect the result. I have assumed the evaporative efficiency of the coke at 5½lb. of water evaporated per lb. of coke. A very small advantage is gained in reduction of engine-room expenses by placing your central station at Dalmarnock, the point at which fuel is cheapest. On the smaller scale of production, the difference is only ·15 of a penny, and the larger scale of production only ·16d.

Digitized by Google

I have said nothing about the price to be charged for electrical energy, as I do not know whether the Corporation wish to make a profit on the sale of electricity or not; but there is a reasonable certainty that, at the scale I have shown, the electricity can be produced at the figures shown, and that the cost of the works will be as estimated. You will see in my estimated cost of the contract works, Sheet A, I have added an item of 10 per cent. for engineer's fees, drawings, and superintendence. This may appear somewhat excessive; but in this case, as throughout these estimates, I have given what I believe to be a safe figure. Moreover, as doubtless, if these works are carried out by your Corporation, the work will be done gradually, the cost of the engineering and superintendence will become somewhat higher than it would be if the work was given out in one contract and carried out in a year or so.

THE DIELECTRIC CONSTANT OF MICA.*

BY E. BOUTY.

In my experiments on well constructed mica condensers (Carpentier microfarad) I proved † that their capacity varies but little with the duration of charging, even for instance if it is reduced to $\frac{1}{500}$th of a second. I gave, moreover, a formula for calculating these variations or *residual charges* by two observations of each of the two capacities to be utilised. M. Carpentier having kindly placed at my disposal the mica sheets employed by him, I tried to find out whether it was possible to completely characterise their dielectric properties by the aid of one or more constants. The investigation on the standard condensers had shown that the variation of capacity between ·1 second and 1 second is, as a rule, less than $\frac{1}{200}$th; but it still remained to be ascertained if between the same limits and to the same degree of approximation, we could attribute an invariable dielectric constant to mica; that is to say, if the capacity of a sheet of surface S and thickness e is faithfully represented by the formula

$$e = \frac{k\,S}{4\pi e}$$

with a constant value for k. The thickness e was always less than ·01 cm. and S was always more than 50 sq. cm. With the degree of approximation obtainable, it was superfluous to have recourse to the artifice of the guard-ring. The measurements were made by a

* *Comptes Rendus*, Vol. CXII. No. 17. † *Ibid*, Vol. CX., p. 1,362.

Digitized by Google

very simple method based on the employment of the capillary electrometer of M. Lippmann, and of an auxiliary microfarad condenser; it was an immediate outcome of the method employed by me in measuring residual charges.*

The sheets to be tested were first of all silvered by the Martin process. The silver was eroded from the edges by nitric acid, and by repeated washing and drying the free surface was deprived as thoroughly as possible of all trace of electrolyte. Finally, the edges were varnished with shellac and the condenser dried at a temperature of 140°C. The following values of k were obtained :—

S Sq. cm.	e μ†	k
49·50	14·75	7·91
65·34	29.09	8·00
65·11	34·88	
66·41	50·75	7·91
64·15	89·00	8·09
	Mean value ...	7·98

In a direction normal to the plane of cleavage *mica therefore possesses a well-defined dielectric constant*, for which the figure 8 may be adopted. It will be noticed that this number is more than three times the square of the mean index of mica, and that from what has been said before, the deviation would diminish but slightly if the duration of the charging period were reduced to $\frac{1}{500}$th of a second.

If it is sought to determine the dielectric constant of mica with sheets of tinfoil, very discordant and far too small values are obtained for k. Moreover, the capacity is considerably augmented when weights are applied. These effects are due to the presence of an irregular layer of air between the tin and the air. If we suppose this double layer of air to have an average thickness of only 5 μ, it is equivalent to a layer of mica eight times as thick,‡ and its presence reduces by one-half the apparent dielectric constant of a sheet of mica 40 μ thick. It is only necessary to establish continuity between the mica and the tin by the interposition of a drop of distilled water or of absolute alcohol§ in order to recover the normal dielectric constant.

With regard to residual charges, there did not appear to me to be any specific difference between the sheets tested. But for the same silvered sheet the residual charge varied so enormously with the condition of the unmetallised superficial layer that it is impossible to be absolutely certain on this point. For instance, it was sufficient on several occasions to wash well in water and then dry for 10 minutes at 140°C. to reduce to one-quarter the residual charge of a sheet which had already been kept for several hours at this temperature. *The incontestable origin of large residual charges is the electrolysis of foreign bodies situated in the superficial layer.*

By repeated attempts I always succeeded in reducing the residual charge formed by charges of two seconds and five minutes duration to values varying from $\frac{1}{60}$th to $\frac{1}{100}$th of the principal charge; that is to say, about one half the residual furnished by the different subdivisions of the Carpentier microfarad condenser which I investigated previously.

LEGAL INTELLIGENCE.

National Telephone Company v. Andrew Erskine Muirhead.

In the Court of Session at Edinburgh, on Wednesday, proof was heard before Lord Kyllachy, in an action by the United Telephone Company and the National Telephone Company, Oxford-court, Cannon-street, London, against Andrew Erskine Muirhead, merchant, Cart Forge, Crossmyloof, Glasgow, for the purpose of having the defender interdicted from infringing the pursuers' telephone patents, ordained to pay £500 damages, and ordained to deliver up for destruction all instruments that infringed the pursuers' patents. In his answers, the defender admitted that he had, with the knowledge and approval of the pursuers, used "Ader" transmitters and receivers for experimental purposes. The pursuers' averments were denied.

The pursuers were represented by Mr. Graham Murray and Mr. Dickson, and the defender by Mr. Asher, Q.C., and Mr. Watt.

Some days before the proof a minute was put in on behalf of the defender, in which he admitted having supplied to certain firms—Messrs. Merry and Cunningham and J. and P. Coats and John Chalmers—"Ader" and "Berthon" transmitters and "Ader" receivers; that these were supplied for the purposes of experiment during the currency of the pursuers' patents; that the "Ader" and "Berthon" were practically the same; that the sale of the "Ader" or "Berthon" transmitters was an infringement of the pursuers' second patent (the carbon transmitter), and that the sale of the "Ader" receiver prior to December 9, 1890, was an infringement of the pursuers' first patent (the magnetic receiver).

This left for proof only the question of whether instruments were supplied for experimental purposes, and, if so, whether this constituted an infringement of the patents; and also the question of damages.

On Tuesday evening the defender, in respect that one patent had expired, and that the other would expire in July, offered to consent to the pursuers' obtaining interdict; to deliver to them infringing instruments in his possession; and to pay £50 damages and expenses as between party and party.

Mr. GRAHAM MURRAY, in opening the case, said the legality of the pursuers' letters-patent was admitted by the defender. There was, therefore, no contest as to the instruments in question held by the defender being an infringement. The controversy arose through the defender saying that the instruments were supplied for experimental purposes, while the pursuers maintained that they were not for experimental purposes, in the ordinary sense of the words, and even if they were that would make no difference. The first witness called was

Mr. JOHN BREWIS, chartered accountant, Edinburgh, who deponed that, having examined the defender's books he found 87 telephones supplied before the date of the action. With the exception of two all these were supplied prior to December 9, 1890. In the ledger he found sums stated as having been paid for the instruments.

Cross-examined by Mr. ASHER: There was nothing in the entry to show that the money was received for Ader or Berthom receivers or transmitters.

SAMUEL THOMAS TURTLE, of Turtle and Appleton, Wandsworth, deposed that in 1890 he saw in the papers that the defender had some connection with long-distance telephones, and on September 8th he wrote to the defender, and found that he had telephones for sale. In the course of correspondence the defender made reference to the patent running out in December, and that if they had them fixed up before December there would be some risk in the matter. In reply, witness wrote that as their telephones were out of the way, and not likely to be seen by people, they did not mind running some little risk. On second thoughts they did not run the risk. Instruments were supplied, but he could not tell of what name they were. They were got in September, but they were not fitted up until after the patent had run out.

ADAM FERGUSON CLEMENTS, telegraph superintendent, North British Railway Company, deponed that in September, 1890, he received a circular and letter from the defender, asking to be allowed to send a couple of instruments for inspection. Witness replied that he had instruments from the Telephone Company, and it was no use the defender sending any. The defender pressed the matter, and ultimately he sent for trial, on 7th November, a pair of the cheapest Ader instruments, with two Poinery receivers and two Ader receivers. Afterwards, on 23rd December, he got a good many more. None of them were yet paid for.

Cross-examined: Their use was wholly experimental. He never understood that he had to pay for them. That was never in contemplation.

In reply to the Judge, counsel explained that up till 9th December, 1890, the Ader and Berthon telephones were infringements of the pursuers' patent. After that date the Ader receiver and magnetic transmitter were set free; the other parts, the Ader carbon transmitter and the Berthon transmitter and receiver, remained infringements up till July.

Mr. MURRAY said he might not be able to prove damage in one sense, but he might show that there had been much in another. The defender had ground-baited the trade in the whole country. He had gone to the railway companies with an instrument, and said that if they thought that would suit them the moment the patent expired they might give him a chance. He had no right to do that.

ROBERT MAIN, of Merry and Cunningham's, deponed that some telephones were supplied to the firm by the defender. They had been handed over to the Mr. Watson, of the Telephone Company, who replaced them by instruments of their own. The instruments were used for ordinary commercial work between the office and the works.

Cross-examined: They were first put up in July, 1890. He knew they were French instruments. A charge was made upon them after they were put down, some alterations being made upon bells. An account was rendered for them. The Telephone Company replaced them free of charge.

WM. HOWARD WINTERBOTHAM, the English solicitor of the pursuers, deponed that he had been engaged in the various litigations in connection with their patents. Early last year the defender communicated with the pursuers' Glasgow office as to certain French instruments, and suggested their being put into use. A correspondence ensued, in the course of which it transpired that the instruments imported from France by the defender were infringements of the pursuers' patents. Accordingly witness wrote him demanding that he should return them to France, or proceedings would be taken against him for infringement. The defender was anxious the pursuers should take up the French instruments. There was nothing new about them. After that correspondence, the defender did not send the instruments back to France, and the pursuers insisted upon them being sent to them. The defender delivered up some instruments, which the pursuers understood were the whole. They found afterwards that the defender was still advertising the instruments. In his circular the defender stated that he was selling the same instruments which were in operation between Marseilles and Paris. That, in witness's opinion, included the Edison transmitter, covering the "Ader" transmitter, the patent for which did not expire until July 30th this year. From witness's practical knowledge of the business, he considered that the sending of circulars by the defender to the railway companies was injurious to the pursuers' business. The profit on a set—a transmitter and a receiver—would be from £6 to £8

* *The Electrician*, Vol. XXV., Aug. 15, 1890, p. 415.

† μ = ·001 millimetre.

‡ It follows from this that in constructing standard condensers of tinfoil far more mica is employed than is necessary, which uselessly increases both their size and weight.

§ This experiment demands special precautions to prevent the electrolyte reaching the edges. It does not lend itself to accurate measurements.

Digitized by Google

DANIEL SINCLAIR, manager of the pursuers' Company, said that the defender's proceedings in sending instruments to the railway companies was injurious to the pursuers. Before the expiry of the patent, the profit upon the sale of an instrument was from £7 to £8, and when it was let it brought a rent of £1 or £1. 10s. Altogether the Company had suffered damage of from £400 to £500.

Cross-examined: He did not know a customer of the pursuers who was induced to take telephones from the defender instead of from them, but in the case of Messrs. Coats, the fact that they were asked by the defender to buy telephones induced the pursuers to lower their rental for instruments. All over the rentals were reduced. It was the practice in this case to reduce the rentals on the approach of the expiry of the patents. They wished to keep on good terms with their customers, and reductions were made to persons who were not approached by the defender, and before this case arose. His estimate of damage was made upon the footing that customers, such as the Midland Railway, kept back orders until after the patent expired in consequence of the defender's proceedings.

Mr. GRAHAM MURRAY said that at luncheon-time a tender had been made by the defender. He had delayed accepting it until Mr. Winterbotham had had an opportunity of explaining in the witness box the cause of raising the action. Now, he thought it his duty to accept the tender, which was that the pursuers should get interest as craved, that they should receive any infringing instruments in the defender's possession, and that the defender should pay £50 damages and expenses as between party and party. He moved the Court to pronounce judgment in terms of the settlement.

Judgment was pronounced accordingly.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May* 9, 1891.

Traction by Alkaline Accumulators.—The electrical sensation just now is a storage battery traction system that actually promises to lead to useful results. This statement may appear almost incredible, but experiments that have been in progress for something like a year, and a public trial in Philadelphia on Monday last, furnish good grounds for encouraging such a belief. The system in question is the invention of two New York electricians, Messrs. Waddell and Entz, and embodies several very excellent features. In the first place, the lead battery with all its concomitant disadvantages has been abandoned, and the motive power is furnished by 100 cells of the alkaline accumulator, similar to that introduced in France by Desmazures. During the early experimental period Messrs. Waddell and Entz met with considerable difficulty from the causes which damaged the reputation of the alkaline battery in France—the increase of resistance owing to oxidation of the copper and losses on open circuit. By furnishing the porous copper of the positive plate with a backing of dense copper, which is entirely unaffected during the operation of the cell, the resistance is kept down and the porosity of the copper is so great that there is not much chance for irreversible oxidation. The parchment paper envelope has been abandoned in favour of a textile covering that answers the same purposes and is less liable to deterioration. The result of these changes has been that the battery does not lose perceptibly on open circuit, and its resistance is very nearly constant. The liquid, of course, is caustic potash, and the negative plated perforated iron. The standard cells weigh 30lb., are 5in. by 7in. by 11in. in dimensions, and have an internal resistance of about ·001 of an ohm, the plates, of course, being in multiple. The electromotive force averages somewhere near ·8 of a volt, and a capacity of 800 ampere hours is claimed. Actual tests show the weight of the battery per electrical horse-power hour delivered to be between 55lb. and 60lb. The experiments tried in Philadelphia were on a line three miles long, with curves and grades as high as 5½ per cent. The car had operated with entire success over this line for some little time before the public trial, and makes an average speed, including stoppages, of about 10 miles per hour, with an expenditure at the power station of about one electrical horse-power hour per car mile. A part of these excellent results is due to the lightness of the entire car equipment, the batteries weighing 3,000lb. and the motor only 1,150lb. The motor possesses some peculiar characteristics of its own; its armature is a Gramme ring 21½in. in diameter, with internal field-magnets energised by a single magnetising coil along the axis of the machine; at each end of the core of this coil is a four-armed spider, with pole-pieces at the extremity, forming four north and four south poles alternating in position. The four brushes connect the armature in multiple arc. The motor is rated at 20 H.P., can be worked considerably above this, and has its point of maximum efficiency at an output of about 15 H.P.; at this point the commercial efficiency, without gearing, is 88·4 per cent.; at an output of 4 H.P. the efficiency is 80 per cent., and at 25 H.P. 86½ per cent. The machine thus has an excellent working range of efficiency, runs without sparking, and altogether is giving a very good account of itself. Its speed for 10 miles per hour car speed is about 450 revolutions per minute, and its armature pinion gears directly into the axle gear. The regulation is effected partly by changing the arrangement of the cells, and partly by cutting out part of the field coil. A switch is provided for throwing the motor into use as a charging dynamo when the car is running downhill, or when it is desired to bring it to rest. The cells of these cars are thrown into multiple series, and a certain amount of energy is restored to them; the inventors claim from ordinary roads something like 10 per cent. gained from this source. A more important advantage secured by this arrangement is the capital braking effect, either by stopping the car or graduating its motion down hill. Altogether, the experiments with this motor car leave one with the impression that it is at least a promising subject for further and more extensive trials. Currents as high as 300 amperes were used in the experiments, but the armature conductors are of ample cross-section and the heating was not at all severe. The total equipment, batteries and motor, is not heavier than the motors employed on the standard cars operated on the trolley system.

Transmitting Power from Niagara to Chicago.—One of the subjects under discussion with reference to the exposition to be held in Chicago is the possibility of transmitting power from Niagara Falls. The distance is about 500 miles, and, of course, alternating apparatus similar to that proposed for use at the Frankfort Exhibition would have to be used. With the advantage of the German experiment on a large scale, such an enterprise should not be unsuccessful if the expenses were not too heavy to be readily met. There will be no difficulty, probably, in securing the apparatus from the manufacturers, but the cost of line might be a formidable obstacle. The project is certainly worth looking into and will be discussed freely long before the time for executing it arrives.

Chicago Exhibition.—Everything with reference to the location of the electrical section of the Chicago Exhibition is as yet somewhat undecided. The plans of buildings which have been published recently may have to be entirely abandoned or very much modified, as the feeling now is that the electrical exhibits should be consolidated as far as possible, and not scattered as the architects' fancy would dictate.

CORRESPONDENCE.

ELECTRO-MAGNETIC INDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In a note referring to my Paper on Magnetism in your current issue, you remark that our method of test could be improved, "as suggested by Prof. Ayrton," by winding the two magnetising coils on the same part of the ring.

I should be sorry if a false impression were created by your remark, and would therefore call your attention to the fact that, in my Paper, in reference to Fig. 1, I expressly state that the coils are *always* superposed.

What Prof. Ayrton said was, that if the *secondary* were wound under the primaries next the iron there would be no correction necessary for induction other than that in the iron. This is perfectly true; but, for practical reasons, it is more convenient to put the secondary outside; and the error is quite negligible until the permeability of the iron becomes comparable with that of air.

You also suggest imitating the load currents in a transformer by winding a coil carrying a heavy current like a non-inductive resistance round the iron; but wound thus, the coil would have absolutely no effect as regards the "B-H curve." Leakage is beside the question. It will vary with the design of each transformer, and cannot be taken account of in a general research such as ours.

When our researches leave *iron* and come to *transformers* the leakage question will become all important.

Dr. Sumpner has pointed out to me that I have used "dynes" erroneously as the C.G.S. unit of H. *What* it really is, no one has yet been able to inform me.

I should like here to express our indebtedness to Messrs. W. J. Goolden and Co., who very kindly put the resources of their factory at our disposal for the purposes of this research.—Yours, &c.,

ERNEST B. VIGNOLES.

Woodfield Works, Harrow-road, W.,

TWISTED TELEPHONE LINES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have pleasure in replying to Mr. Ullett's strictures on my letter of May 1st. If in doing so I have to trespass unduly on your space, I trust that the importance of the question to telephonists will be accepted as a sufficient excuse.

I confess that I regret the extension of the "twist" as being not only unnecessary but mischievous. No good engineer uses two bolts where one would suffice, and on the same principle telephonists should not construct perpetual aerial corkscrews where an occasional reversal answers just as well. The extension of the "twist," so far as the National Telephone Company is concerned, is not based on any question of comparative efficiency, but is due to the belief of the Directors that sooner or later their system will be taken over by the Post Office, and that a higher valuation will be placed on work executed in conformity with Post Office practice. In pursuance of this policy their staff were ordered early in 1890 to conform to Post Office ideas—or supposed ideas—in this and other particulars. I say "supposed ideas" because the Post Office do not adhere so rigidly to the "twist" as the National Directors imagine.

From the tenour of Mr. Ullett's criticisms I feel sure that he has had no experience whatever of the "cross," and that his ideas on the subject are not of the clearest. Otherwise he would not imagine difficulties where none exist, and base his arguments on the erroneous supposition that crossings must be both numerous and intricate. But taking his points seriatim:—

1. *Greater first cost of twist.*—The number of additional insulators, special brackets, and cross-connections required is very small. In erecting a loop, the two wires are run straight through, like ordinary telegraph wires. Afterwards the wires are cut, terminated, and crossed at the proper places. The cost of such a loop is not appreciably greater than two single wires run side by side. I could adduce instances to show that this is not the case with the "twist." The National Telephone Company keep very careful records of the cost of their trunk lines, and when I say that not only were the crossed trunks more efficient and cheaper to maintain, but invariably cheaper in first cost—in some instances ridiculously so—than the twisted ones, I am asserting that which is well within my knowledge, and is susceptible of proof by an inspection of the Company's accounts.

2. *Unsightliness of Twist.*—This Mr. Ullett admits, but says that it does not matter. I cannot agree with him. Telephone trunk lines have frequently to be carried past gentlemen's houses, and across estates. In such cases, as in dealing with road trustees and county councilmen, sightliness is of material moment, as any telephone manager who has to procure wayleaves knows.

3. *Greater Liability to Faults in Twist.*—As I stated in my former letter, I have never erected a twisted line. My experience—and it has been a bitter one—is derived entirely from having to exercise what patience was possible while sections of twisted trunk lines beyond my control remained interrupted for days together, and while subscribers were refusing to pay their subscriptions, and threatening to withdraw from the exchange in consequence of frequent breakdowns in the service. But I have often inspected twisted routes, and it seems reasonable to attribute, to some extent, the greater frequency of faults to the difficulty in regulating so as to maintain a constant vertical distance between the wires. On a model line, with equally-spaced posts of the same height, and wires regulated by the spring-balance, something approaching perfection could be attained, but where is the telephone trunk route to be found where such conditions obtain? Routes nearly always follow public roads, where equal spans are impossible, and where the poles may be anything between 28ft. and 60ft. high. Regulating on such a line is easy enough when one wire hangs exactly beneath another, and any neglect can be detected by the engineer as he walks along the road; but with the "twist" neither the man who pulls up nor the man on the road can do more than guess at what is being done, since the vertical distance between two crossing wires cannot be accurately judged from above or beneath. Variations of temperature destroy what symmetry there was to begin with, and so contacts occur. A notable instance of the disastrous effect of snow on twisted loops occurred a few years ago. A 50-mile route, made up of 25 miles of "twist" and 25 miles of "cross," was subjected to a heavy snow-storm throughout its whole length. On the "twist" section every loop was interrupted for several days, and it was weeks before even passable order was restored, for the whole had to be gone over and regulated. On the 25-mile section of "cross" there was not a fault of any kind. The copper wires had stretched with the weight of the snow, but their relative distances were unaltered, and no regulation was necessary. The dropping from a higher to a lower arm incidental to the twist is equivalent, so far as the strain on the wire at the upper insulator is concerned, to an increase in the length of the span. This does not matter much in ordinary weather, but with severe frost, adhesive snow, or heavy gale, it tells, and, according to my experience, very seriously. To make a twisted line equal in strength to a crossed one the spans must be shorter, which means extra poles and insulators, or the wires must be slacker, which means contacts. This 50-mile route belonged to the National Telephone Company, but a twisted loop 50 miles long leased to the same Company by the Post Office in 1883, was prolific of faults; indeed, for the first eight or nine months after erection, a week rarely passed without an interruption in spite of the specially anxious care of the linemen. In fact, it was the experience derived from this loop which first caused me to question the wisdom of twisting.

4. *Greater Difficulty in Finding Faults on Twist.*—My experience of prolonged interruptions on twisted sections has been extensive, and in such cases the engineers and linemen responsible always took refuge in the plea that faults were so difficult to find. Mr. Ullett says that a lineman has only to watch the

Digitized by Google

apparent cross in the wires as he walkes along. This is virtually an admission of the difficulty which I say exists, for how can a man be expected to keep his eye with unflagging attention on a constantly moving cross for mile after mile? With one loop the effort must be considerable; with 12 or 14 loops on the same poles it would be arduous in the extreme. The London readers of *The Electrician* have an opportunity of judging for themselves just now by looking along Bartholomew-lane, either down from Threadneedle-street or up from Lothbury. Two twisted loops are suspended over Bartholomew-lane, and an apparent cross exists above that thoroughfare. Let the observer imagine 12 loops instead of two, and pity the man who has to follow such an arrangement, for 25 miles or so, over hill, dale, and housetops, with the sun in his eyes, perhaps, charged with the duty of separating real from apparent crosses. Besides, it is frequently impracticable for a man to follow a line exactly without trespassing and without great loss of time, and sometimes he will get a shady avenue or background of trees that will deprive him of the light necessary to trace his crosses. With straight wires a cross is noticed instinctively, because it is a break in the monotony of parallel lines. It may be seen from an express train, and under all circumstances is easier to find. Of course, the proper way to localise contacts is not by making men tramp the routes, but by testing from the stations; but that refinement for telephone companies is not yet.

5. *Re-arrangement of Routes.*—My statement was based on the experience of having a trunk route rendered next to useless for several weeks on and during a change from short to long cross-arms. The work was under the care of a great advocate of the "twist," and I felt bound to accept his assurance that the trouble was unavoidable. Nothing of the kind need happen with the "cross." So few crossing places are needed that their position may generally, for the time being, be ignored without detriment to the service. The re-arrangement is as simple as with single straight wires.

If Mr. Ullett, with whose position I have not the honour to be acquainted, has control of any telephonic system, and wishes to acquire actual experience of the "cross," I shall be happy to place drawings and full particulars at his disposal. He will find that much longer sections than 10 miles can be made so silent that any disturbance will have to be specially listened for; that crossed trunks of any length are electrically as good as twisted ones, and mechanically much better; in short, that twisted loops are as unnecessary as twisted lamp-posts. If Mr. Ullett specially objects to the cross-connections themselves, let him run his wires straight for several miles, and then devote a few spans to a corkscrew of orthodox fashion. That would be better than perpetual revolution.

With regard to Mr. Ullett's remark about two single wires on the same arm, I can only say that his experience has been different from my own, and would appear, at the same time, to have been singularly unfortunate.—Yours, &c.,

A. R. Bennett.

May 18, 1891.

TRADE NOTES AND NOTICES.

Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.]

"THE ELECTRICIAN"

ELECTRICAL TRADES' DIRECTORY & HANDBOOK for 1891.

The 1891 edition of our well-known Directory and Handbook is ready, price 5s., postage extra. The book consists of over 900 pages, and has entailed this year a heavy amount of work. The Handbook Division contains a mass of most useful information. The Directory Division consists of 430 pages, and contains a very carefully compiled Alphabetical and Classified List of Firms and Persons engaged in the Electrical and Allied Trades in all parts of the world. This Division has been corrected up to date, and the book is thoroughly reliable, the very numerous changes which take place at the beginning of the year being incorporated. By the aid of this Directory, makers of Electrical Machinery, Apparatus, Instruments, Fittings, Sundries, Novelties, and other goods, may safely communicate direct with probable customers without the annoyance and great expense consequent upon using books which are mere lists of Members of Scientific Societies repeated again and again. The Colonial and Foreign Division of this Directory will be found extensive and reliable. *Orders should be forwarded at once.*

In the course of a few days "The Electrician" Company will publish "The Electrician" Primers in two volumes, price per volume 2s. paper covers, 2s. 6d. cloth.

Tenders Invited.—Particulars will be found in our advertisement columns of the request for tenders by the Gas Committee of the Manchester Corporation for lighting the Town Hall with electricity, reference to which was made in the Trade Notes in our last issue.

———. Tenders are required by the St. Pancras Vestry for supplying and erecting arc lights, columns for same, and road shelters, either together or separate. Copies of specifications, schedules and designs can be obtained at the office of Prof. Henry Robinson, C.E., the engineer to the Vestry, 13, Victoria-street, S.W., on and after to-morrow (Saturday), the 23rd inst.; and tenders are to be sent in to Mr. T. E. Gibb, the Vestry Clerk, Vestry Hall, Pancras-road, N.W., by June 1st. Particulars will be found in our advertisement columns.

Messrs. Oakden and Sharpe.—This firm notify us that they have added to their wholesale ironmongery business at Grimsby an electrical department.

Bristol's Recording Pressure Gauge.—This very simple and inexpensive instrument for giving a continuous record of the pressure in a boiler should be very useful in central station work. As there are no multiplying devices, it is not likely to get out of order. They are being supplied by Mr. J. W. Phillips.

Automatic Electric Railway Signal Company, Limited (in Liquidation).—A meeting will be held in the Small Sale Room, Exchange Station-buildings, Liverpool, on June 22nd, at 2:30, to receive an account of the winding-up.

Electric Company (Limited).—A meeting will be held at Messrs. J. Lord and Co.'s, 3, Bucklersbury, E.C., on June 18th, at 12, to receive an account of the winding-up,

Simplex Electrical Syndicate (Limited).— Resolutions were passed at a meeting held on April 22nd, and confirmed on May 7th, that this syndicate be voluntarily wound-up.

Woodhouse and Rawson Electric Supply Company of Great Britain (Limited).—Resolutions were passed at a meeting held on March 20th, and confirmed on April 17th, that this Company be voluntarily wound up, and that Messrs. Albert Hoster, T. H. Lambert, and F. L. Rawson be appointed liquidators.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

Note.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

April 27, 1891.

7,225. G. A. Nussbaum. London. Improvements in telephonic transmitters or microphones.

7,242. H. Bate. London. Electrically charged pills.

7,261. E. Dénorus. London. Improvements in and relating to the electro-deposition of metal upon fabrics, plants, animals, and the like.

April 28, 1891.

7,278. G. Percival. Cork. Improvements in electric switches and circuit closing and opening devices.

7,283. A. R. Bennett. London. An improved system of telegraphy and telephony.

7,292. H. Nehmer. London. An adhesive electrode for the application of electricity to animal bodies.

7,308. P. E. Singer. London. Improvements in musical instruments actuated by electricity.

7,315. M. W. Dewey. London. Improvements in method of and apparatus for electrically supplying hot water for consumption and heating purposes.

Digitized by Google

331. C. D. ABEL. London. Improvements in telephones of the Ader system (Société Générale des Téléphones, Reseaux Téléphoniqu et Constructions Electriques, France).

W. P. THOMPSON. Liverpool. Improvements in and relating to dynamo-electric machines (F. Tischendörfer, United States).

April 29, 1891.

7,35 . J. P. BAYLY. London. Improvements in electric railway systems (D. G. Weems, United States).

5. E. ATKINS and W. ATKINS. Birmingham. Improvements in electrical fittings.

7,372. R. BOLTON and W. C. MOUNTAIN. London. Improvements in means or apparatus for actuating hammering, caulking, rock-boring, or like percussive machinery by the rid of electricity.

7,427. W. W. HORN. London. Improvements in electric time-locks (M. J. Flowers, J. E. Jones, and C. W. Price, United States).

7,433. Sir D. L. SALOMONS, Bart. London. A leakage detector or insulation tester, to be employed in the testing of electric lighting conductors and other leads.

7,434. A. NODON. London. Improvements in the electrolysis of chlorides, and in the utilisation of the liberated chlorine for the manufacture of chlorates, hypochlorites, and other compounds.

April 30, 1891.

7,479. E. E. KELLER. London. Improvements in underground conduits for electric railways.

7,493. E. A. SPERRY. Chicago. A system of mounting dynamos and motors upon rotary axles.

7 518. T. A. BULLOCK and A. C. BROWN. London. A new or improved combined transmitting and receiving sounder telegraph instrument or "Unigraph."

7,529. G. SHANN. London. A dynamo electric machine.

May 1, 1891.

7,531. A. CUTHBERT. London. An insulation cutter, or improvements in combination cutting pliers for insulated electric wires.

May 2, 1891.

7 596. F. NUSCH and S. NAWRATZKI. Liverpool. Improvements in or connected with telephones.

7,603. J. S. YULE and C. W. STEWART. Glasgow. Yule's electric signalling apparatus for passenger trains.

7,614. T. P. WALKER. London. Regulating the brilliancy of electric incandescent lights.

7,634. G. W. HUMPHREY. London. Improvements in electric alarm clocks.

May 4, 1891.

7,667. H. L. CALLENDAR. London. Improvements in dynamo-electric machines and electric motors.

7,688. A. SAUNDERS. London. A spiral filament for incandescent electric lamps.

7,697. C. P. ELIESON. London. Improvements in electrical accumulators or storage batteries.

7 699. H. J. ALLISON. London. Improvements in machines for making storage battery plates (P. Kennedy and C. J. Diss, United States).

7,700. H. J. ALLISON. London. Improvements in storage battery plates (P. Kennedy and C. J. Diss, United States).

7,701. H. J. ALLISON. London. An improved storage battery plate and method of making same (P. Kennedy and C. J. Diss, United States).

7,702. A. HOSTER. London. Improvements in or relating to the construction of electric lamp holders and other electric appliances.

May 5, 1891.

7,728. J. LEA. Northampton. Improvements in lamp-posts or columns for electric arc lighting.

7,755. H. H. LAKE. London. Improvements in and relating to electric motors or dynamo-electric machines (The Crocker-Wheeler Electric Motor Company, United States).

7,762. C. J. VAN DEPOELE. London. Improvements in reciprocating electric engines.

7,778. W. P. THOMPSON. Liverpool. Improvements in or connected with electric conductors (J. B. Williams, United States).

7,781. P. BOUCHEROT. London. A method or means for converting an electric current of constant periodic electromotive force into a current of constant intensity, and a current of constant intensity into one of constant difference of potential.

May 6 1891.

7,821. J. B. HAMILTON. Edinburgh. An improved machine for the conveyance of parcels and the like.

7,831. H. REYNIER. London. Improvements relating to the manufacture of insulating partitions for use in primary and secondary batteries.

7,850. W. W. HORN. London. Improvements in automatic telephone exchanges (A. B. Strowger, United States).

May 7, 1891.

7,857. F. BRYAN and WOODHOUSE AND RAWSON UNITED (LIMITED). London. Improvements in the construction of rheostats or similar electrical instruments.

7,858. C. S. SHELL and WOODHOUSE AND RAWSON UNITED (LIMITED). London. Improvements in switches used for electrical purposes.

7,863. R. B. HUTCHINSON, W. B. HUTCHINSON, and J. HUTCHINSON. London. An improved method of and means for cultivating land by the employment of an electric current.

7,878. F. J. ROWAN and W. MCWHIRTER. Glasgow. Improvements in appliances for preventing ignition of gases in connection with dynamos, motors, or other electrical apparatus.

7,911. G. S. GRIMSTON. London. An electric switch.

7,912. G. S. GRIMSTON. London. An electric capstan.

May 8, 1891.

7,937. C. W. COX. Liverpool. Improvements in or relating to electric resistance devices for measuring electric currents.

7,949. P. GOWARD. London. Improvements in secondary batteries.

7 954. G. POORE. London. Improvements in and relating to electric call apparatus.

7,960. R. D. SANDERS. London. Improvements in apparatus for use in the manufacture of metal tubes, cylinders, or other articles by electro-deposition.

7,970. E. A. WAHLSTRÖM. London. Improvements in distributing electric energy.

May 9, 1891.

7,976. G. BINSWANGER. London. Improvements in handles for electric light switches.

7,979. G. E. B. PRITCHETT. Stortford. Improvements in electric accumulators or secondary batteries.

8 009. G. POORE. London. Improvements in and relating to electric call apparatus.

8,031. H. HOWARD. London. Improvements in apparatus for heating and welding by the electric arc.

8,034. A. L. SHEPARD. London. An improved device for facilitating the connection and disconnection of electrical conductors.

SPECIFICATIONS PUBLISHED.

1890.

6,083. GORDON. Electric propulsion of tramcars. (Price 1s. 1d.)

6,726. VON HEFNER-ALTENECK. Electrical timepiece, &c. (Price 8d.)

COMPANIES' MEETINGS & REPORTS.

The West Coast of America Telegraph Company (Limited).

The 14th Ordinary General Meeting of this Company was held on Friday, May 15, 1891, at Winchester House, Old Broad-street, the chair being occupied by Alfred Marshall, Esq.

The SECRETARY (Mr. Fred. L. Robinson) read the notice calling the meeting and the minutes of the last meeting.

The CHAIRMAN then said: With your permission we shall take the balance-sheet and report as read. The accounts which we present to you to-day give a very clear insight into the business which the Company has done during the year 1890, and, although it has not yielded as handsome returns as the year 1889, still the result must, as you will agree with me, be considered very satisfactory. The only item that calls for explanation is that of the gross earnings of the Company, which, although nearly the same as those of the year 1888, fall short of those for 1889 by about £20,000. This is to be accounted for by the repairing steamer earning

Digitized by Google

about £5,400 less than in the previous year, owing to our neighbours having built and used their own steamer instead of employing ours as heretofore, and by our having earned much less on messages between Europe and the East Coast of South America, because there has been no repetition in 1890 of the interruptions that occurred on the Eastern lines during 1889, and which gave us such exceptionally large traffic receipts in that year. You will observe an increase of about £1,000 in the interest account; this is due to larger investments of the reserve fund. The negotiations referred to in the Directors' report are progressing favourably, and I have great confidence in their resulting soon in placing this Company in a firmer position than it was in before—to resist and cope with any competition that may arise. As these negotiations may entail the addition to our Board of one or two Directors, we have purposely not yet filled up the vacancy which occurred some time ago. If we cannot hold out hopes that the exceptionally large profit of 1889 will be repeated, we would ask you to bear in mind that in all telegraphic business one thing is certain, and that is, when an important distant community has once been accustomed to daily communication with Europe, it becomes an increasing necessity to them, and that, therefore, the total traffic with the West Coast of South America, may be looked upon as likely to increase, though, perhaps, suffering a temporary check from the present revolution in Chili—and that, consequently, we may expect the share of that traffic which we may secure likewise to increase. I am glad to be able to inform you that we received a few days ago, and since the issue of our report, the news that our cables were in working order from Lima as far south as Caldera, leaving only the most southern sections between Caldera and Valparaiso sealed by the Chilian authorities. Before putting the formal motion for the adoption of the report of the accounts, I shall be very glad to answer any question which any gentleman might have to ask; only, as regards the negotiations, my tongue is tied, as it would not be to the advantage of the shareholders that any premature information should be divulged with regard to them.

Mr. LAMONT inquired whether they were able to carry on business now to Europe in all the existing difficulties. He would not ask any question with regard to the negotiations, as he saw that it would not be advisable to do so.

The CHAIRMAN: Does any other gentleman wish to ask any question? After a pause, and no one rising to address the meeting, he continued: With regard to our present business since January 1st, we have been rather more fortunate than we could have expected. I think it was on January 15th when the revolution broke out, and the Chilian Government took possession of all the telegraph lines. They stopped our business for a time, but we received compensation from them. They paid us $15,000 for stopping our business, and then they made a contract with us to pay us $2,000 a day for the use of our wires and cables on the coast. This was a very handsome consideration. This contract came to an end on March 18th, so that we have been doing a very fair business—much better than could have been expected up to March 18th. Since then the most southern sections, we believe, have not been worked, but as the cables between Callao, Lima, and Caldera, are now in perfect working order, we are earning on them. I cannot tell you the exact amount that we have been earning since then, but I fancy it will pay our expenses from that time.

Mr. LAMONT: And our opponents' work.

The CHAIRMAN: Our opponents' cables are laid as far as Valparaiso. Their cable between Iquique and Valparaiso is not working, but they are working between Lima and Iquique. They are conveying any commercial messages that may arise between Iquique and Europe. It is only a fraction of the general traffic. Of course, all traffic from the other stations—from Mollendo, Arica, and Antofagasta, and so on—go over our lines.

A SHAREHOLDER said he thought that the reserve fund was a very handsome sum, and that all the shareholders would appreciate the prudence of the Board with regard to it. He thought, however, that it was customary in most companies to publish a list of their investments. He presumed that this was optional, but he thought as the amount was large that it would be satisfactory to the shareholders to see what it was invested in.

The CHAIRMAN: The investments are all made after consulting our auditors; but we will take into consideration the question of giving further details in future reports. I now formally propose

"That the report and accounts for the year ended December 31st, 1890, now presented, be received and adopted."

Mr. HENRY ROBERTS: I beg to second this.

The CHAIRMAN put the motion in the usual way, and it was carried unanimously. Continuing, he said: I have now to propose

"That a final dividend at the rate of 1 per cent. per annum, free of income tax, making 2½ per cent for the year, be now declared, payable on the 20th inst."

Mr. FREDERICK WALTERS seconded the resolution, which was carried unanimously.

On the motion of Mr. WALTERS, seconded by Mr. PACE, the retiring Directors, Mr. Alfred Marshall and Mr. Henry Roberts, were re-elected, as was also Mr. J. Weise, the retiring auditor, on the motion of Mr. PACE, seconded by Mr. TAYLOR.

Mr. WILLIAM PAYTON: Before we leave will you allow me to propose a vote of thanks to yourself for your conduct of our affairs? We hope that by your management we shall be in a better position in the future. If you are in the Chair on a future occasion I trust to see realised the hopes which you have given us to-day.

Mr. LAMONT: I have much pleasure in seconding the motion, and I congratulate you and the gentlemen on that side of the table on the more hopeful spirit you have evinced to-day than you showed when we last met together. I think that you were then under a cloud, and you seemed almost prepared to give up the fight. That, however, is not according to the British plan, and I am glad to see that you have exerted yourself, and that you are going to engage in the struggle, and are not going to be put down by any Yankee opposition.

The motion was carried unanimously.

The CHAIRMAN: I am very much obliged to you for re-electing me a Director, and for your kind expressions towards myself. I can assure you that I shall do my best; and, as I have to-day, I think, shown in my speech, I have much more confidence in the future than I could have had six months ago.

Mr. LAMONT said he hoped it would all be realised.

The CHAIRMAN: If anything important should happen for which your consent is required, it will, of course, be laid before you.

The proceedings then terminated.

Western Counties and South Wales Telephone Company (Limited).

The sixth annual ordinary general meeting of this Company was held on Saturday, at the Grand Hotel, Bristol, Mr. C. Nash (chairman) presiding.

The notice of meeting having been read by the General Manager and Secretary (Mr. H. F. Lewis),

The CHAIRMAN, in moving the adoption of the report and accounts, dealt with the question of capital expenditure, which, he said, in 1890 was £24,415, or £2,402 less than in 1889; but while the expenditure was less the rate of increase of the gross revenue was much larger. The advance in net revenue was still more striking, being the largest increase of any year in the history of the Company. The increase was £3,240, which was about 35 per cent. on the previous year's net revenue Then, again, the working expenses were over £400 less than the annual increase since 1885. With regard to their plant, not only had it been well kept up, but, as stated in the report, the substitution of the more durable and efficient copper-bronze wire had been extended. Many improvements had been made at various centres designed to give the subscribers the latest and best possible service. The balance, after paying interest on debentures and dividend on preference shares, would admit of a small dividend on the ordinary shares, but the Directors, after full consideration, had decided to advise carrying forward the balance of £2,677, after placing an additional £500 to the credit of the reserve fund, which would then amount to £2,200. The Chairman then spoke of the several points of the report bearing on the increase in the number of subscribers, the increase in wire mileage, and the increase of trunk messages, and contended that those facts pointed conclusively to the steady and continuous progress of the Company. Having alluded at length to their trunk system and its working, he said he hoped they would agree with him that the considerable outlay of £46,883 on trunk lines had been fully justified by the results. He found that between Cardiff, Newport, and Swansea there were in April 13,384 calls, and, as each call was answered, the total communications were 26,768, or more than 1,000 a day for the 26 working days of the month in that district alone. During the past year their trunk system had been extended *viâ* Gloucester and Worcester to Birmingham and the Midlands and the North of England. In the local exchanges he found that there was an increase of more than half a million calls in 1890 over 1889, and, as each call was answered, more than six million communications were made. Not only was the business continuous, but it was going on more rapidly than ever, and, considering the near expiration of patents and the rumours of competition, this fact was a striking proof of the firm hold the telephone had on the public mind. Eighteen weeks of the current year had passed, and in that time they had an increase of £1,845, against £1,504 in the corresponding period of last year, which showed a large weekly interest. Such continued and increasing advance was most satisfactory. There was another point, and that, he thought, was a very important one. The greater part of their agreements were for long periods, and had a considerable unexpired time to run. From a carefully-prepared table he found that at the end of last November they had 1,104 agreements for the year, and under 2,141 for periods ranging from one to nine years. Those unexpired periods of agreements represented on the 30th November last a contract rental to the amount of between £86,000 and £87,000, constituting an element of great stability for the Company. Those agreements had been secured by charging lower rates for the longer periods. They would agree with him that in case of a purchase by the Post Office or the National Company those long unexpired agreements, and the great general elasticity of their business, would constitute important elements of value. It only remained for him to state that one of their patents expired last December, and that the other would run out on the 31st July. That would relieve them from the payment of a considerable amount of royalty, and without committing themselves then in any precise figures, he might say that it was their intention to reduce the rates payable by their subscribers to at least the amount of the remission of the royalty, and they hoped that that reduction would lead to a considerable increase of business. This reduction would probably take effect from the 1st of August.

Mr. M. WHITWILL seconded the resolution, and said that the figures given by the Chairman showed conclusively that what they said years ago had proved to be true—that the business public were beginning to recognise the telephone as one of the necessities of existence.

In reply to a SHAREHOLDER, who asked why, seeing that there was enough money to do it, a dividend had not been declared on the ordinary

Digitized by Google

shares, the CHAIRMAN said the local Directors did propose a small dividend, but on consulting the members of the Board in London the latter declined to sanction a dividend being made on the ordinary shares.

The report having been adopted, the CHAIRMAN then moved that a dividend at the rate of 6 per cent. on the preference capital be declared, which was seconded by Mr. FEDDEN, and carried unanimously.

The CHAIRMAN next moved that £500 be transferred from the balance to the reserve fund, which was seconded by Mr. POLE, and carried unanimously.

Mr. Charles Nash and Mr. R. Cory were re-elected Directors; and Messrs. Hudson Smith, Briggs, and Co., of Bristol, were re-appointed auditors.

The remuneration of the Directors was fixed at £600 for the ensuing year, and in acknowledging the same, the CHAIRMAN bore testimony to the excellent services rendered by the General Manager and Secretary, Mr. H. F. Lewis.

After the usual vote of thanks to the Chairman, the proceedings terminated.

Panulcillo Copper Company (Limited).

The 23th ordinary general meeting of the members of this Company was held on Thursday, at Winchester House, Old Broad-street, under the presidency of Sir John Pender, K.C.M.G., the Chairman of the Company.

The report stated that the operations at Panulcillo in the 12 months ended December 31, 1890, had resulted in a net profit of £7,037, of which £785 had been placed to the reserve, in accordance with the Articles of Association, leaving £6,252 to the credit of profit and loss account, which it was proposed to carry forward, the money being required to pay for the purchase of the Condesa Mine and other developments.

In proposing the adoption of the report and accounts, the CHAIRMAN said that when he last had the pleasure of addressing the shareholders, 12 months ago, it was just after the collapse of the great copper speculation, which caused a complete disorganisation of the copper market. He had, however, stated that, after careful consideration, the Directors thought that a much more satisfactory state of things would soon arise, and, although the growth might be slow, it was likely to be sure. This, more or less, had been realised, and the price of copper since then had advanced to a point which was likely to be maintained, and which was upon the whole a satisfactory price for Panulcillo. He also pointed out last year that the labour question was a serious one, as was also the difficulty of obtaining carbonate ores. All these questions were being solved now; labour was more abundant, and the Directors had secured an important carbonate mine (the Condesa), which was likely to prove very valuable. With a little further extension in this direction, they were looking forward altogether to a very much better state of things. The price of copper had remained satisfactory, and appeared likely to remain so, everything seeming to indicate that they might, for a considerable time at least, look on £50 as a probable, at least an average, price for Chili bars, while values would probably range somewhat above this figure, which was all they could desire. In briefly referring to the new markets for copper, he said that the other day, when he was addressing a large meeting of shareholders of the Metropolitan Electric Light Company, he had occasion to point out that during the 15 months of that Company's existence it had put down 90 miles of insulated copper wire; and when they looked at the large number of similar companies springing up, not only in London, but in every important town in this and other countries, it would give them some idea of the large quantity of copper that is being used, and will eventually be used, for electric lighting purposes.

The report and accounts were unanimously adopted, and the retiring Directors, Sir John Pender and Mr. F. Walters Bond, were re-elected.

The Consolidated Telephone Construction and Maintenance Company (Limited).

The following is the Directors' report to be presented at the tenth annual general meeting of the Company, to be held at the Cannon-street Hotel, E.C., on Thursday, the 28th inst., at 12 o'clock:—

The Directors have pleasure in submitting to the shareholders the report and accounts of the operations of the Company for the year ended March 31, 1891, the latter showing a net profit of £11,573. 8s. 9d., which, with the amount carried forward from last year, leaves a balance of £13,416. 6s. 8d. for disposal, after making provision for doubtful debts. The Directors propose to deal with this amount as follows, viz., to pay a further dividend of £7 per cent. for the half year on the ordinary shares, and £6 per cent. on the preference shares, making, with the interim dividend paid in November last, £6 per cent. for the year on both descriptions of shares; writing off the sum of £530. 3s. for depreciation of plant, machinery, and furniture, £63. 16s. 8d. from cost of new building, and the sum of £436 from goodwill and patent rights, thus leaving a balance of £1,716. 4s. 10d. to carry forward.

The lawsuit in Belgium, relating to the patents in which the Edison Gower-Bell Telephone Company is interested, is still in the hands of the solicitors, but it is hoped that a decision will soon be arrived at.

One of the patents for telephones held by the National Telephone Company expired on the 9th December last. This has had the effect of enabling the Consolidated Company to sell telephones to the public; and, so far as your Board can judge, an increasing business is in prospect. The shareholders may rely upon every effort being made to keep the Company's manufactures well in advance of both home and foreign competition.

The Subsidiary Companies continue to make most satisfactory progress, as is shown by the following statement:—

	Year ending March 31st.					
	Subscribers.		Rental.		Increase.	
	1890.	1891.	1890.	1891.	Subscribers	Rental.
			£	£		£
Telephone Company of Austria	2,868	3,263	18,100	20,500	395	2,400
Anglo-Portuguese Telephone Co....	1,915	2,074	12,232	13,458	159	1,226
Total increase for the year ...					554	3,626

In accordance with the Articles of Association, the following Directors retire by rotation, and, being eligible, offer themselves for re-election, viz., Sir Alexander Armstrong, K.C.B., &c., and Arthur Henry Baker, Esq. The Auditors, J. G. Griffiths, Esq., F.C.A. (Messrs. Deloitte, Dever, Griffiths, and Co.), and A. E. Green, Esq., F.S.A.A., also retire, and offer themselves for re-election.

NEW COMPANIES REGISTERED.

ART WORKSHOPS (LIMITED).—Registered with a capital of £30,000 in 1,100 guaranteed ordinary shares of £10 each and 19,000 ordinary shares of £1 each. Object: To acquire the business carried on at 58A, Brompton-road, 31, St. George's-place, and 5, Wilton-crescent-mews, Brompton, and to carry on the business (amongst others) of electrical engineers.

ALBION CLAY COMPANY (LIMITED).—Registered with a capital of £65,000 in £10 shares. Objects: To acquire the business of a brick and pipe manufactory, carried on under the title of the Albion Clay Company, at Woodville, Leicester, and to carry on the business (amongst others) of electrical engineers.

GEORGE CROSSLEY (LIMITED).—Registered with a capital of £15,000, in £5 shares. Object: to acquire the business of an engineer and iron-founder, carried on at the Albion Works, Cleckheaton, Yorkshire.

FOWLER INSULATOR SYNDICATE (LIMITED).—Registered with a capital of £6,000, in £1 shares (of which 500 are deferred), to adopt an agreement dated April 25, 1891, for the acquisition of the patent for "Insulators and Appliances for Suspending Wires or Aerial Telegraphs," and to manufacture the same.

REFRACTORY ORES REDUCTION COMPANY (LIMITED).—Registered with a capital of £30,000 in £1 shares. Object: To acquire certain patent rights, inventions, lands, estates and properties, and to carry on generally the business of metallurgists, miners, smelters, assayers, &c.

TOWNEND BROTHERS (LIMITED).—Registered with a capital of £25,000, in £1 shares. Object: to acquire the business of George Townend, of Payne's-lane, Coventry, and to carry on business as engineers, machinists, toolmakers, &c.

TREALAW ENGINEERING FOUNDRY COMPANY (LIMITED).—Registered with a capital of £10,000 in £10 shares. Object: To carry on business as mechanical engineers, brass and iron founders, and dealers in metal goods of every description.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the past week amounted to £5,176.

CITY AND SOUTH LONDON RAILWAY COMPANY.—The traffic receipts of this Company for the past week amounted to £665.

RUSTON, PROCTOR, AND COMPANY (LIMITED).—The Directors recommend a dividend for the past 12 months of 7½ per cent, with £1,049 to be carried forward.

SOCIETE ANONYME DES MINES ET FONDERIES DE ZINC DE LA VIEILLE MONTAGNE.—The report for 1890 of this Company, which has its seat at Angleur, near Liège, and has also zinc works in Germany, declares a dividend of 37½ per cent. The results for 1890 are the most satisfactory since the forming of the Company in 1837.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended May 15, 1891, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,170.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this Company for the two weeks ended May 15th show a decrease of £154 as compared with the corresponding period.

WOODFIELD SYNDICATE (LIMITED).—This syndicate has been formed with the intention of carrying out some experiments on a large scale in connection with electricity, under the supervision of Messrs. W. T. Goolden and Co., without interfering with the manufacturing business carried on by them.

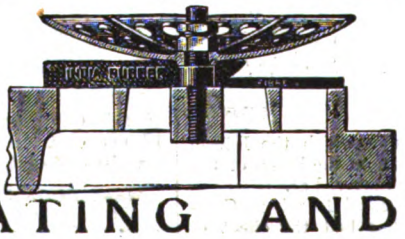
NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept. 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 680.—Vol. XXVII. FRIDAY, MAY 29, 1891. Price Fourpence.

NOTES.

At the last meeting of the Institution of Electrical Engineers, Sir William Thomson recalled attention to the tendency of alternating currents to avoid the central portions of metallic conductors, thereby giving rise to an increase of resistance which has been occasionally alluded to under the name of the "skin effect." This phenomenon would be of great importance if currents of high frequency were in use, but, except with very heavy leads, the magnitude of this effect is of little moment with ordinary alternating currents. The alteration of resistance is only a few per cent. with leads of one centimetre in diameter, and as the whole loss in the leads is only a small fraction of the energy supplied, the diminution, owing to this cause, of the commercial efficiency of the installation is so small as to be rarely worth the expense of avoiding.

With low-tension work bare conductors can be used, and the effect diminished by making the section rectangular, instead of circular. With high-tension insulated conductors it is rarely necessary to use heavy leads, and even if this were the case it would, as Mr. Siemens pointed out, be inadvisable to make the conductor like a tube, for the increased size for the same section of copper would involve a greater expense in the insulating and protecting portions of the cable, and the interest on this extra cost would more than counterbalance the slight saving in economy. The practical importance of the effect has been over-estimated, and some of the remedies which have been proposed appear to be worse than useless. The mere stranding of the conductor does not obviate the difficulty if, as is usually the case, the inner strand is confined to the central portion of the wire; and any attempt at braiding the different strands, so that each one is sometimes within and sometimes outside the others, would be too costly to be worth while. Moreover, stranding the conductors produces an increase of resistance by itself, as the current has to progress spirally over a greater distance than the actual length of the stranded cable, and the extra resistance caused in this way may be as great as that due to the so-called skin effect.

Sir William Thomson probably surprised many of his audience by declaring such a decided preference for the low-tension direct-current system of supply, because it possesses greater simplicity than its alternate-current rivals. This quality must, doubtless, characterise any final engineering system, for only simple mechanical considerations and rule-of-thumb methods can permanently retain great importance. Electrical engineering, however, is not yet so stereotyped as the other branches of the industry, and direct-current systems have had a long start of alternate-current ones. In one respect the very complexity of the alternate-current system is an advantage, as it yields itself the more readily to new applications. It therefore seems too soon to forecast the future. Sir William Thomson's advocacy of the Edison system may encourage further litigation by Edison's representatives in this country; but as Prof. Kennedy points out in our correspondence columns this week, the Edison patent is not so far-reaching as it is imagined to be.

It must be confessed that, in spite of the amount of time which has been devoted to the action of transformers, the theory of them is still in a very unsatisfactory state. The assumptions which are usually made in describing their behaviour in mathematical language seem to be quite unjustifiable when closely examined. According to Mr. Evershed, two types of transformer exist, the real transformer which runs lamps, and the phantom which dwells in mathematical minds, and possesses constant coefficients, and an immaculate iron core. There appears to be nothing constant or certain about these strange members of the electrical family. The ratio of transformation not only varies to some extent as the load is changed, but may be altered very considerably by the use of condensers. Electrical engineers cannot yet be said to agree whether it is better to make their magnetic circuit closed or open, and the general confusion of the subject has been lately increased by the suggestion, based, it is true, on somewhat dubious experimental evidence, that the hysteresis loss in the core of a constant potential transformer diminishes as the load is increased. The latter phenomenon, if true, is of little commercial importance, as the diminution of the loss occurs when the need of getting rid of it is least; but it so revolutionises our notions of magnetism that the question of its existence is a most desirable one to settle as soon as possible, more especially as it seems to point out the possibility of getting rid of hysteresis losses altogether.

Some of the more important tests of transformer efficiency made in this country and in America have been carried out by means of Mr. Blakesley's split dynamometer method, and on the authority of some of these measurements is based the idea that the hysteresis losses alter with the load. The split dynamometer is, after all, only a modification of the ordinary wattmeter, with the advantage that no error is introduced owing

Digitized by Google

to the self-induction of the coils; but the great fault of the method lies in the assumption that no magnetic leakage occurs in the transformer, and, in our opinion, this error is serious enough to invalidate the tests. At the last meeting of the Physical Society, however, Prof. PERRY directly challenged these views by endeavouring to show that the formula given by Mr. BLAKESLEY is true, even on the assumption that magnetic leakage occurs. To establish his point he proceeded to treat the transformer after the method of MAXWELL, assuming its coils to possess constant coefficients of self and mutual induction, and advanced the opinion that the abandonment of this method by HOPKINSON, who proposed to consider only the induction in the core and the current in the coils, was a move in the wrong direction. Although, no doubt, the simplicity of the latter method is very much diminished when leakage occurs in the transformer, and MAXWELL'S method renders it easy to take account of leakage by merely assuming less mutual induction between the coils, yet we think that if MAXWELL had lived longer he would have been the first to abandon his own method on finding the great variations which actually occur in his coefficients when iron is present in the cores. The Paper gave rise to a vigorous discussion, in which the balance of opinion appeared to be against Prof. PERRY. Mr. BLAKESLEY himself thought that there must be somewhere an error in the argument, and Dr. SUMPNER, Mr. SWINBURNE, and Prof. AYRTON also spoke against the method of proof.

AT the same meeting Prof. PERRY showed a new form of steam indicator which seems likely to be very useful. In the ordinary Richards indicator the vibrations of the cord introduce errors which become very noticeable at high speeds. This fault is entirely got rid of in Prof PERRY'S instrument, which has, moreover, the advantage that the diagram, instead of being traced by a pencil on an oscillating cylinder, is traced by a spot of light moving on a flat surface. The diagram can thus be seen while it is being drawn, and, if any change takes place in the action of the engine, an eye accustomed to indicator diagrams can at once detect what has happened. The apparatus is extremely simple; an ordinary galvanometer mirror being subjected to two rotary motions at right angles to one another, one caused by the motion of the piston in the cylinder, and the other by the pressure of the steam against a disc to which the mirror is attached. A common oil lamp gives enough light to produce a spot sufficiently bright to be seen in an ordinary engine-room, the whole arrangement can be set up permanently like an ordinary pressure-gauge, and with an engine running at a sufficiently high speed, the spot of light moves so fast that the entire diagram is continuously visible. The great advantages of this instrument for experimental work on engines are obvious, and in many cases it may prove of great value to have a permanent indicator attached to engines doing regular work.

THE electric light is as yet not nearly so important a rival of gas as the younger competitor, paraffin. DAVY observed the electric arc in 1802, and showed it on a fair scale in 1810. Two years after the invention of the Bunsen battery, in 1842, the electric light was publicly exhibited with a Foucault hand-regulated arc lamp. GREENER and STAITE patented their lamps in 1846 and 1847, and it was not until the latter year that YOUNG struck oil in Derbyshire. The supply ran out in three years, and his celebrated patent for extracting it from coal or shale was dated 1850. The American supplies were not utilised until 1856, by which time SERRIN had patented his highly developed arc lamp. Paraffin, however, quickly shot ahead, on account of the obvious simplicity of its use. Slight alterations in old lamps were soon made, and in spite of the dangerous properties of the imperfectly refined oil and the badly designed lamps, mineral oil became largely used. But the numerous accidents which attended both the handling and the consumption of it gave it a bad name—a name so bad, indeed, that petroleum is hardly ever mentioned. The name of one of the many distillates and residuals, and one which properly belongs to a wax discovered by REICHENBACH, in 1830, has been borrowed, and is commonly applied to it in this country, and, as with gelatin, it is customary to drop the final *e* in scientific literature. In America the name kerosine is given to the oil when freed from the dangerous benzines and other undesirable products.

THE proper construction of lamps for burning mineral oil has been carefully investigated by Sir FREDERICK ABEL, and most of his recommendations have been accepted by manufacturers of the better class of lamps. Very little information has transpired about the details of the lamentable accident which caused the death of three persons last week, but it seems that the lamp was upset, and thus set fire to the room. Another fatal accident occurred this week owing to the explosion of a lamp. Several mechanical devices of a somewhat clumsy appearance have been contrived to liberate an extinguisher in case a lamp is overturned, and it is probable that explosions caused by overheating of the burner could be prevented by a fuse which would act in the same way. With all these ingenious self-acting safety-devices, it may be possible to make the use of mineral oil no more dangerous than gas, but neither of these sources of illumination can ever compare with electric light in this respect. It is to be hoped that the remarkable use of oxygen as a restorative after suffocation, which is so graphically described in a recent number of the *Nineteenth Century*, will be speedily adopted. It would seem that the three lives lost on Saturday last might have been saved if it had been employed.

ON Tuesday last one of the *employés* at the Bourse office of the London-Paris Telephone line, having rung up the English end, took up the receivers and put them to his ears, with the unexpected result that he received a severe shock. The accident was probably due not to a direct lightning discharge, but to induction. The English land line is thoroughly protected by both plate protectors and vacuum tubes, and, beyond a few slight indications which were noticed before these were fitted, there has been no trouble at this end. The London-Paris wire differs, of course, from ordinary telegraph lines in that it is completely insulated from the earth, and any metallic circuit so insulated is liable to these static disturbances; but they have been seldom noticed before, probably because the circuits have not been of sufficient length.

In another column we publish a draft memorandum on the preparation of the Clark cell. This has been drawn up for the consideration of the Electrical Standards Committee of the Board of Trade. The illustration which accompanies it is not official, but we have prepared it from the description, and believe that represents the type of cell used at the Cavendish Laboratory. Mr. GLAZEBROOK, to whom we are indebted for a copy of the memorandum, would be glad to hear the result of the experiences of any who may try to set up cells in accordance with these directions, that he may compare their results with his own.

THE somewhat stuffy atmosphere and comparative gloom of the City and South London Railway have a marked influence on the receipts whenever we are indulged with a little sunshine and warmth; indeed, a chart of this Company's weekly traffic returns would prove, at least, as accurate a record of the general state of the weather as a file of the daily prognostications of the Meteorological Office, the receipts falling as the barometer rises, and *vice versa*.

Telephonic Extensions in France.—The telephone trunk wire between Paris and Troyes (110 miles) was opened to the public on May 16th.

Appointment Vacant.—Applications are invited for the appointment of demonstrator of electrical engineering at the Yorkshire College, Leeds.

Commercial Cable Company.—This Company has opened an office in Cardiff, at 100, James-street, Bute Docks, with special wire service in connection with its cables.

Projected Application of Electric Traction in Berlin.—The engineer of the Grosse Berliner Tramway Company, Herr Fischer Dyck, has been sent to investigate the electric tramways in Budapest, with a view to the adoption of a similar system in Berlin.

National Telephone Company v. Andrew Erskine Muirhead.—Mr. Erskine Muirhead draws our attention to an error in the report of this action which appeared in our last issue, pp. 83-84. Mr. Muirhead states that he only agreed to pay £5 damages and costs, not £50.

Palermo Exhibition.—The electric lighting of this Exhibition has been secured by Messrs. Moleschott and Schilling, representing Siemens and Halske, of Berlin. Five 60 kilowatt machines are to be put down for the purpose, a sixth dynamo being used for running various motors throughout the building.

An Electric Light Carbon Trust.—Another step in the progress of the Carbon Trust was taken, says *Whipple's Reports*, of New York, early in the month, when the general offices of the Standard Carbon Company, of Cleveland, were removed to the National Carbon Company's building. The Carbon Trust is a reality, but thus far the projectors have not raised prices.

The Telephone in Chicago.—The Chicago Telephone Company contemplates the adoption of an improvement which will result in the disappearance of the magneto. If the proposed device comes into use it will only be necessary to place the telephone to the ear to ring up the exchange, the movement of the receiver-hook sending a signal to line. The proposed modification is estimated to effect a saving of some £8,000.

Barnet.—At the meeting of the Local Board, on the 5th inst., a discussion took place on the subject of the future lighting of the town. The Lighting Committee reported that no tenders had been received for electric lighting, and they recommended that offers be invited from persons willing to carry out any system—electricity, gas, oil, or even candles. A long discussion ensued; and ultimately it was decided that a deputation should wait on the Gas Company, and tenders be advertised for.

Cable Extensions.—The new cable (250 miles) connecting France and Corsica, which was manufactured at the Seyne Works, has been successfully laid by the "Charente."——The telegraph steamer Monarch arrived in Lerwick harbour on Friday afternoon last from Westray, Orkney, and immediately commenced laying a cable between Lerwick and the island of Brissay, a distance of about one mile. The work was completed the same evening.

Provisional Order Bills.—Mr. Campion, the examiner in the House of Commons, has found compliance with Standing Orders in the case of various Provisional Orders relating to the electric lighting of Edinburgh, Paisley, Preston, Liverpool (Toxteth Park), Birmingham, Cardiff, Scarborough, Torquay, Tunbridge Wells, Withington, Exeter, Ipswich, Newport (Mon.), Poole, Hertford, Bromley, Kingston-on-Thames, Weybridge, Camberwell, Islington, Southwark, Westminster, Wandsworth, Clerkenwell, Chelsea, and Woolwich.

Electric Rivetting Patents.—A decision has just been given by the Examiner of Interferences, in the United States Patent Office, in which priority of invention of the art of electric rivetting, and also of the apparatus for practising this art, was awarded to Mr. Elias E. Ries, of Baltimore, the other party to the interference being Prof. Elihu Thomson. The evidence showed that Mr. Ries was not only the first to file, but also the first to reduce the inventions to practice, and upon these and other facts brought out the decisions awarding priority to Mr. Ries were based.

Damage by Lightning.—A terrific thunderstorm broke over the western quarter of Dartmoor last week, and extended across the valleys of the Tamar and Tavy. At Tavistock cattle were killed and several trees struck. The Midlands were also visited by a storm of some severity. At Droitwich several trees were stripped, and at Nottingham the storm resulted in the ringing up of the fire brigade. At Alnwick, lightning struck the chimney of the armoury magazine and stores of the 3rd Northumberland Fusiliers, demolishing it and cracking the wall almost to the ground, notwithstanding that on a chimney-stack on the same roof there was a lightning conductor. On Wednesday, this week, a labourer working in a field at Ewerby, near Sleaford, was struck by lightning and killed.

Central London Railway.—The time has expired for lodging petitions in the House of Lords in opposition to the Central London Railway Bill, and only 10 petitions have been deposited. The petitions now deposited do not indicate any serious opposition to the preamble of the Bill. Four petitions are from owners of property who did not appear in the House of Commons, whilst the remaining six are from petitioners who lodged petitions in the House of Commons, but who, with the exception of the London County Council and Mr. Maurice Powell, a landowner, did not appear to support their petitions. The Commissioners of Sewers, who opposed this scheme in the House of Commons, have now presented a petition against any alteration being made in the Bill.

Paper Insulation for Electric Light Conductors.—One of the newest insulating materials, says the *Electrical World* of New York, is the paper insulation of the Norwich Insulated Wire Company. The wire is insulated with strips of the strongest manila paper, wound on in overlapping spirals. The paper is expressly made for the Company, and arrives at the works in rolls containing a web from half a mile to five miles in length, and weighing from 20 to 90lb. per ream. These rolls are cut into strips about half an inch wide and, perhaps, a mile long. After the wires are covered they are compounded with a material called "sydite." They are then braided, and again treated with a modification of the same compound, and are polished and reeled ready for the market.

A New Use for the Electric Light on Board Ship.—By the aid of the electric light, the Botanical Mission despatched some months since by the authorities of Kew to the West Indies were extricated from an embarrassing dilemma. They had with them a number of Wardian cases containing vine cuttings and Gambier plants, which it was deemed very desirable to introduce into the islands; but, unfortunately, cold weather set in, and the efforts to convey these tender plants, which had so often ended in failure, threatened once more to result in

Digitized by Google

disappointment. The difficulty was that if kept on deck they would be inevitably destroyed by the low temperature; while if taken below the absence of light which is so necessary to the existence of the delicate Gambier plants was almost certain to be equally fatal. Under these circumstances it occurred to Mr. Morris to avail himself of the electric light, of which there was an installation on board the Atrato. The experiment proved in every way successful. Mr. Morris is of opinion that the use of the electric light for the safe passage of valuable plants during the winter months is capable of being greatly extended.

Frankfort Exhibition.—The catalogue of the Exhibition, compiled by Herr Alexander Askenasy, is a very creditable production. The first part (215 pages) contains a short *résumé* of the preliminary proceedings leading up to the Exhibition. Then comes a list of all the members of the Exhibition Committee and the names of the jury. This is followed by the catalogue proper, which gives each exhibit in alphabetical order, and indicates where it is to be found. Some idea of the trouble taken by the compiler may be gathered from the fact that there are 394 exhibitors, and that one firm alone has over 100 different numbers assigned to its goods. Some hundred more exhibits will have to be added when the Technical Department opens on June 15th. To the alphabetical list of 162 pages succeeds a numerical one, and this, again, is followed by a table of contents, so that visitors to the Exhibition will have three separate ways of tracing exhibits. By way of appendix is also given—(1) a description of the Exhibition workshops, (2) a description of the Exhibition lighting arrangements, (3) a description of the boilers, engines and dynamos, and (4) a ground-plan of the Exhibition.

The Jablochkoff Patent.—Another venerable patent, says *Industries*, has joined the majority. An attempt was made to galvanise it into life again, but its existence could not be prolonged beyond its allotted days. Little was known of this patent until recently, when it was suddenly brought forward to cover transformer distribution. The owners did not attempt to deal harshly with the public, and their moderation secured royalties instead of opposition. While the loss of the patent may be regretted from the owner's point of view, it may be as well to mention that Jablochkoff did not invent transformer distribution. Though his claim may have covered it, it was a mere accident. His object was not to transform from a high to a low pressure, nor to save copper in leads; but to allow a number of lamps to be run off one machine, or, in the words of those days, to "subdivide the electric light." He thought that by putting the lamps on secondary circuits of transformers in series, they might go out accidentally without destroying the continuity of the dynamo circuit. His transformer was specially designed to be short-circuited completely. He makes a merit of having the copper in metallic contact with the iron of the core throughout. We merely mention this as one of the too common cases where the merits of an invention are taken away from the real inventor and given to some earlier worker who has unintelligently stumbled on something like it, without in the least understanding its capabilites.

An Arc Lamp-Pole Device.—The need of trimming arc lamps daily first led to the use of a light, but sufficiently long, ladder, which the trimmer carried with him on his rounds. Later the upper rounds of this ladder were transferred to the poles, and the general adoption of the so called polesteps shortened the portable ladder, and threatened to stop its use altogether. As a substitute for this ladder a few detachable polesteps may be used, as they are much more easily carried about. Such a device has lately been put on the market, says a writer in the *Electrical Engineer* of New York, and reminds the writer of some home-made polesteps which he saw in use in an eastern town. It was at a place where the circuits spread out several miles in each direction, and many of the lamps were on the hills some 300 feet above the level of the rest. Such a topography made the carrying of the ladder quite a burden, and the ingenious trimmer soon hit on an easier plan. He drilled three holes into the sides of every pole at about the points where additional polesteps would be placed, slanting the holes slightly downward. Three short wooden pieces, whittled out of a broomstick, formed the steps for which these holes served as sockets. Then, with the wooden pegs hung from his tool-belt by little wire hooks, he started out on his rounds better equipped and yet less loaded down than before.

Institution of Civil Engineers.—At the annual general meeting of this Institution, on Tuesday last, the report of the Council for the Session 1890-91 was read, in which it was stated that an endeavour had been made to identify, in some degree, each gathering with a particular branch of engineering, both in respect to those invited to be present and to the models and other objects of interest exhibited. These receptions were believed to have been most successful, and experience would doubtless suggest directions in which they might be rendered still more useful and attractive in the future. Telford Medals and Telford Premiums have been awarded to Messrs. Ll. B. and C. W. Atkinson and to Mr. R. E. B. Crompton, and a Telford Premium to Mr. W. Langdon. The number of members of all classes, students excepted, on the 31st of March last was 5,150, as against 4,903 on the same day last year, representing an increase at the rate of 5 per cent. Adding the students to the number on the register, the gross total on the books was 6,064. From the balance-sheet appended to the report, it appeared that the receipts during the financial year amounted to £24,274. 8s. 11d. The Council congratulated the members that the House of Lords had upheld the judgment of the Court of Appeal, that the whole of the property of the Institution was exempt from duty, on the ground that it was legally appropriated and applied for the promotion of education and science. In conclusion, reference was made to the action of a committee of members outside the Council, which had resulted in the establishment of an endowment fund for the purpose of perpetuating the memory of the long services of the secretary in the interests of the Institution. It had been decided that the endowment in question, with any future additions, should be applied to the establishment of a "James Forrest Lectureship," it being left with the governing body for the time being to determine the subjects, the periods of recurrence, and all other details connected with such lectureship. The ballot for Council resulted in the election of Mr. George Berkley as president.

The Telephone in Paris.—The subscribers to the Paris Telephone Exchange, whose subscriptions date from a period previous to September 1, 1889, when the State took over the telephone system of the country, have recently been served with two somewhat unpleasant documents. The first, signed "J. de Selves,' runs as follows:—"By Article 5 of your agreement the various instruments composing your telephonic post and the accessories which you have asked for must be supplied by you and at your own expense. When the State took over the Paris system, the authorities allowed you the provisional enjoyment of the apparatus then in your possession. It is now necessary to set this matter right (*régulariser cette situation*). I have the honour to inform you that you will have to arrange with the Société Générale des Téléphones for the purchase of your instruments, from whom you will shortly receive the bill. This Company will be within its rights in taking away your instruments after a period of 15 days, and consequently your communication with the exchange would be suspended until further orders." This circular was soon followed by one from the Société Générale, enclosing the bill for the telephonic apparatus, and intimating that, unless payment was forthcoming within a fortnight, the apparatus would be taken away. Subscribers can, of course, if they prefer to do so, buy new instruments elsewhere; but these, if they contain an induction coil, will have been manufactured by the Société Générale, which, by a recent judgment (see *The Electrician*, Vol. XXVI., March 27, p. 632), has had its monopoly of this device when used in conjunction with the telephone confirmed. The situation is, therefore, somewhat curious; the State possesses a monopoly of the telephonic system of France, but the Société Générale possesses a monopoly of the apparatus. As the *Bulletin International de l'Electricité* remarks, it is a state of affairs which should have been foreseen, and subscribers should have been spared the inconveniences of it.

ELECTROMAGNETIC THEORY.—X.

BY OLIVER HEAVISIDE.

(*Continued from page 783, Vol. XXVI.*)

§ 62. The two laws of circuitation did not start into full activity all at once. On the contrary, although they express the fundamental electromagnetic principles concerned in the most concise and clear manner, it was comparatively late in the history of electromagnetism that they became clearly recognised and explicitly formularised. We have not here, however, to do the work of the electrical Todhunter, but only to notice a few points of interest.

The first law had its first beginnings in the discovery of Oersted that the electric conflict acted in a revolving manner, and in the almost simultaneous remarkable investigations of Ampère. It did not, however, receive the above used form of expression. In fact, in the long series of investigations in electro-dynamics to which Oersted's discovery, and the work of Ampère, Henry, and Faraday, gave rise, it was customary to consider an element of a conduction current as generating a certain field of magnetic force. Natural as this course may have seemed, it was an unfortunate one, for it left the question of the closure of the current open; and it is quite easy to see now that this alone constituted a great hindrance to progress. But so far as closed currents are concerned, in a medium of uniform inductivity, this way of regarding the relation between current and magnetic force gives equivalent results to those obtained from the first law of circuitation in the limited form suitable to the circumstances stated.

If **C** is the density of conduction current at any place, the corresponding field of magnetic force is given by

$$\mathbf{H} = \frac{V\mathbf{C}\mathbf{r}_1}{4\pi r^2}, \quad \ldots\ldots\ldots \quad (1)$$

at distance r from the current-element **C**, if $\mathbf{r}_1$ be a unit vector along **r** from the element to the point where **H** is reckoned. The intensity of **H** thus follows the law of the inverse square of the distance along any radius vector proceeding from the current-element; but, in passing from one radius vector to another, we have to consider its inclination to the axis of the current by means of the factor $\sin\theta$ (where θ is the angle between **r** and the axis), involved in the vector product. Also, **H** is perpendicular to the plane containing **r** and the axis of the current-element, or the lines of **H** are circles about this axis.

But from the Maxwellian point of view this field of **H** is that corresponding to a certain circuital distribution of electric current, of which the current-element mentioned is only a part; this complete current being related to the current-element in the same way as the induction of an elementary magnet is to the intensity of magnetisation of the latter. Calling the complete system of electric current a rational current-element, it may be easily seen that in a circuital distribution of rational current-elements the external portion of the current disappears by mutual cancelling, and there is left only the circuital current made up of the elements in the older sense. We may, therefore, employ the formula (1) to calculate without ambiguity the magnetic force of any circuital distribution of current. This applies not merely to conduction current (which was all that the older electricians reckoned), but to electric current in the wider sense introduced by Maxwell. But the result will not be the real magnetic force unless the distribution of inductivity is uniform. When μ varies, we may regard the magnetic force of the current thus obtained as an impressed magnetic force, and then calculate what induction it sets up in the field of varying inductivity. This may be regarded as an independent problem.

In passing, we may remark that we can mount from magnetic current to electric force by a formula precisely similar to (1), but subject to similar reservations.

§ 63. But this method of mounting from current to magnetic force (or equivalent methods employing potentials) is quite unsuitable to the treatment of electromagnetic waves, and is then usually of a quite unpractical nature. Besides that, the function "electric current" is then often a quite subsidiary and unimportant quantity. It is the two fluxes, induction and displacement (or equivalently the two forces to correspond), that are important and significant; and if we wish to know the electric current (which may be quite a useless piece of information) we may derive it readily from the magnetic force by differentiation; the simplicity of the process being in striking contrast to that of the integrations by which we may mount from current to magnetic force.

To exemplify, consider the illustrations of plane and spherical electromagnetic waves of the simplest type given in §§ 53 to 61, and observe that whilst the results are rationally and simply describable in terms of the fluxes or forces, yet to describe in terms of electric current (and derive the rest from it) would introduce such complications and obscurities as would tend to anything but intelligibility.

Now, Maxwell made the first law of circuitation (not, however, in its complete form) practically the definition of electric current. This involves very important and far-reaching consequences. That it makes the electric current always circuital at once does away with a host of indeterminate and highly speculative problems relating to supposititious unclosed currents. It also necessitates the existence of electric current in perfect non-conductors or insulators. This has always been a stumbling-block to practicians who think themselves practical. But Maxwell's innovation was really the most practical improvement in electrical theory conceivable. The electric current in a nonconductor was the very thing wanted to coordinate electrostatics and electrokinetics, and consistently harmonise the equations of electromagnetism. It is the cardinal feature of Maxwell's system, and, when properly followed up, makes the insulating medium the true medium in the transmission of disturbances, and explains a multitude of phenomena that are inconceivable in any other theory (unless it be one of the same type). But let the theoretical recommendations (apart from modern experiments), which can only be appreciated after a pretty close study of theory, Maxwellian and otherwise, stand aside, and only let the tree be judged by its fruit. Is it not singular that there should be found people, the authors of works on Electricity, who are so intensely prejudiced against the Maxwellian view, which it would be quite natural not to appreciate from the theoretical standpoint, as to be apparently quite unable to recognise that the fruit has any good flavour or savour, but think it no better than Dead Sea fruit? The subject is quite sufficiently difficult to render understandable popularly, without the unnecessary obstruction evidenced by a carping and unreceptive spirit. The labours of many may be required before a satisfactory elementary presentation of the theory can be given. So much the more need, therefore, is there for the popular writer to recognise the profound significance of the remarkable experimental work of late years, a significance he appears to have so sadly missed. When that is done, then will be the time for an understanding of Maxwell's views. Let him have patience, and believe that it is not all speculative metaphysics because it is not to his present taste. Never mind the ether disturbances playing pranks with the planets. They can take care of themselves.

§ 64. Two or three changes I have made in Maxwell's form of the first circuital law. One is of a formal character, the introduction of the **h** term to express the intrinsic force of magnetisation. This somewhat simplifies the mathematics, and places the essential relations more clearly before the eye. Connected with this is a different reckoning of the energy of an intrinsic magnet, in order to get consistent results.

The second change, which is not merely one of a formal character, but is an extension of an obligatory character, is the introduction of the **h** term to represent the motional magnetic force. In general problems relating to electromagnetic waves it is equally important with the motional electric force.

The third change is the introduction (first done, I think, by Prof. Fitzgerald) of the term to explicitly represent the convection-current or electrification in motion as a part of the true current. Although Maxwell did not himself explicitly represent this, which was a remarkable oversight, he was strongly insistent upon the circuital nature of electric current, and would doubtless have seen the oversight the moment it was suggested to him. Now, there are spots on the sun, and I see

Digitized by Google

no good reason why the many faults in Maxwell's treatise should be ignored. It is most objectionable to stereotype the work of a great man, apparently merely because it was so great an advance, and because of the great respect thereby induced. The remark applies generally; to the science of Quaternions, for instance, which, if I understand rightly, Prof. Tait would preserve in the form given to it by Hamilton. In application to Maxwell's theory, I am sure that it is in a measure to the recognition of the faults in his treatise that a clearer view of the theory in its broader sense is due.

§ 65. The second circuital law, like the first, had an experimental origin, of course, and, like the first, was long in approximating to its present form—much longer, in fact, though in a different manner. The experimental foundation was Faraday's recognition that the voltage induced in a conducting circuit was conditioned by the variation of the number of lines of force through it.

But, rather remarkably, mathematicians did not put this straight into symbols for an elementary circuit, but went to work in a more roundabout way, and expressed it through the medium of an integration extended along a concrete circuit; or else, of an equation of electromotive force containing a function called the vector potential of the current, and another potential, the electrostatic, working together not altogether in the most harmoniously intelligible manner—in plain English, muddling one another. It is, I believe, a fact which has been recognised that not even Maxwell himself quite understood how they operated in his "general equations of propagation." We need not wonder, then, that Maxwell's followers have not found it a very easy task to understand what his theory really meant, and how to work it out. I had occasion to remark, some years since, that it was very much Maxwell's own fault that his views obtained such slow acceptance; and, in now repeating the remark, do not abate one jot of my appreciation of his work, which increases daily. For he devoted the greater part of his treatise to the working out and presentation of results which could be equally well done in terms of other theories, and gave only a very cursory and incomplete exposition of what were peculiarly his own views and their consequences, which are of the utmost importance. At the same time, it is easily to be recognised that he was himself fully aware of their importance, by the tone of quiet confidence in which he wrote concerning them.

Finding these equations of propagation containing the two potentials unmanageable, and also not sufficiently comprehensive, I was obliged to dispense with them; and, going back to first principles, introduced what I term the second circuital law as a fundamental equation, the natural companion to the first. The change is, I believe, a practical one, and enables us to considerably simplify and clarify the treatment of general questions, whilst bringing to light interesting relations which were formerly hidden from view by the intervention of the vector potential **A**, and its parasites J and Ψ.

Another rather curious point relates to the old German electro-dynamic investigations and their extensions to endeavour to include, supersede, or generalise Maxwell by anti-Maxwellian methods. It would be slaying the slain to attack them; but one point about them deserves notice. The main causes of the variety of formulæ, and the great complexity of the investigations, were—first, the indefiniteness produced by the want of circuitality in the current, and next the potential methods employed. [J. J. Thomson's "Report on Electrical Theories" contains an account of many. As a very full example, that most astoundingly complex investigation of Clausius, in the second volume of his "Mechanische Wärmetheorie," may be referred to.] But if the critical reader will look through these investigations, and eliminate the potentials, he will find, as a useful residuum, the second circuital law; and, bringing it into full view, will see that many of these investigations are purely artificial elaborations, devoid of physical significance; gropings after mares' nests, so to speak. Now, using this law in the investigations, it will be seen to involve, merely as a matter of the mathematical fitness of things, the use of another, viz., the first circuital law, and so to justify Maxwell in his doctrine of the circuitality of the current. The useful moral to be deduced is, I think, that in the choice of variables to express physical phenomena, one should keep as close as possible to those with which we are experimentally acquainted, and which are of dynamical significance, and be on one's guard against being led away from the straight and narrow path in the pursuit of the Will-o'-the-wisp.

As regards the terms in the expression of the second law which stand for unknown properties, they may be regarded merely as mathematical extensions which, by symmetrizing the equations, render the correct electric and magnetic analogies plainer, and sometimes assist working out. But some other extensions of meaning, yet to be considered, have a more substantial foundation.

LIGHTNING CONDUCTORS.

BY DR. OLIVER LODGE.

(*Concluded from page 9.*)

Effect of inserting Long Leads in the A portion of the Circuit.

§ 63. So far, the various long wires round the room had been used as alternative path, *i.e.*, had been made to shunt the B spark. I now proposed to insert them into the circuit in another place, so that while they exerted their full effect on the frequency and damping of the oscillations, they should not otherwise directly affect the B spark, which was to be shunted by a distinct and constant conductor.

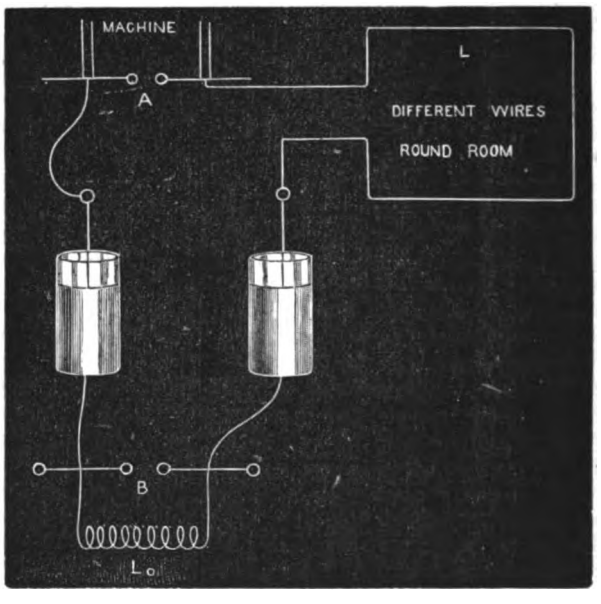

FIG. 11.

For this latter purpose I wound on a glass lamp chimney a spiral of copper wire of the following dimensions:

685 centims. of No 12 copper wire in 39 turns.

Diameter of each turn 5·5 centims. Thickness of wire ·24 centims. Total length of spiral 28 centims. Free ends, 13 centims. the two, attached to spark micrometer. A pair of No. 16 copper wires, 18 inches each, joined the micrometer to the outside coats of the gallon jars standing on insulating stool as shown in Fig. 11.

The spiral was easily detachable, and so the alternate path was either this spiral or nothing.

One or other of the long leads round the room was now used to join the knob of one of the jars to the machine. The knobs of the machine were set 4 centims. apart, and the experiment was ready to begin. Connection shown in Fig. 11.

It was found that under these circumstances (as had often been found before), *i.e.*, with a long lead in the main circuit, the jar to which it was connected was very apt to overflow, *i.e.*, to spark round its edge, a distance of 8 inches; this tendency being more marked when the circuit is formed of

Digitized by Google

good conductors than when the resistance and consequent damping of oscillation is considerable.

The leads inserted in the main circuit were the same as have already been described—viz., about 27 metres of No. 12 and of No 27 of iron, copper, and lead respectively.

October 15th, 1888. The following was the result :—A spark length 4·0 centims.

Lead in Main Circuit.	Alternative Path.	Length of max. B spark.	Remarks.
Thin copper...	None	9·178	Jar does not overflow.
,,	Copper spiral	·763	Jar sometimes overflows.
Thick copper.	None	9·460	Does not overflow.
,,	Copper spiral	approximately ·9	But jar now overflows every time.
Thin iron.....	None	8·0	Decidedly shorter than with copper.
,,	Copper spiral	·745	Jar sometimes overflows.
Thick iron ...	None	9·135	
,,	Copper spiral	·80	Overflows rather often.
Thin lead.....	None	7·525	
,,	Copper spiral	·778	Sometimes overflows.
Thick lead ...	None	8·79	
,,	Copper spiral	·850	Overflows nearly every time.

Thus, unless the circuit is closed by the alternative path, there is no overflow of the jar, but the maximum B spark is very long, about twice as long as the exciting A spark. When the air-gap is bridged by the copper spiral, overflow occurs, but much more easily with the thick copper lead than with the others.

The reason why the B spark is so short is because the main part of the circuit is so long, *i.e.*, because in the approximate formula

$$\frac{B}{A} = \frac{L_0}{L + L_0},$$

because L is much greater than L_0. (L_0 is the inductance of the alternative path ; L is the inductance of the rest of the circuit.)

Long Leads in both A and B portions of Circuit.

§ 64. The same arrangement of jars, &c., was tried again on October 17th, but some one or other of the long leads was used as the alternative path, while another of them, viz., the thin copper, was included in the main or A portion of the circuit. Fig. 11 is to be modified by removing the spiral marked L_0 and substituting another long wire, like L. The remarks appended in the last column of the following table, showing the number of times the B spark occurs and the number of times it fails under given circumstances, are useful as indicating the sharpness of the adjustment and the range of uncertainty.

Alternative path.	Length of B spark-gap in centimetres.	Remarks.
None	7·90	...
Thin iron	1·36	2 B sparks occur in 10 attempts.
,,	1·35	3 sparks in 6 attempts.
Thick copper ...	...	Spits over edge of jar every time.
Thin lead	1·240	2 B sparks pass in 17 attempts.
,,	1·225	2 ,, ,, 8 ,,
,,	1·213	6 ,, ,, 6 ,,
Thick iron	1·162	6 ,, ,, 8 ,,
,,	1·175	2 ,, ,, 7 ,,
,,	1·201	1 ,, ,, 13 ,,
Thick lead	1·075	3 ,, ,, 3 ,,
,,	1·087	3 ,, ,, 6 ,,
,,	1·100	1 ,, ,, 10 ,,

With the thick iron the jar spits rounds its edge pretty often, and with the thick lead it does so nearly every time. With the thick copper, as stated above, it always does so, and hence no satisfactory readings could be taken with it.

Experiments on the Effect of Mutual Induction between A and B portions of Circuit.

§ 65. But since the two leads used in this experiment both went round the same room, and not more than a foot apart, there is some mutual induction between them ; so observations were made, noticing carefully whether the discharge was going the same way round the two wires or the opposite way round. The main circuit conductor was still the thin copper wire, and the alternative path was one of the others. When the current goes the same way in both I call it the concurrent arrangement; when opposite ways, non-concurrent.

The A spark was shortened to 3·5 centims. in order to avoid so much overflowing of the jars.

Alternative path.	Length of B spark.
Thin iron, concurrent arrangement	1·34
Ditto non-concurrent	1·30
Ditto concurrent again	1·33
Thick copper, concurrent	·95
Ditto non-concurrent.....	·84
Ditto concurrent again	·95

Thus the effect of mutual induction was slightly to increase the apparent impedance of the alternative path when its current flowed in the same direction as that in the main circuit. But the effect is not great. The fact is that L and L_0 are both affected together, and so the effect on the ratio $\frac{L_0}{L + L_0}$ is unimportant.

Effect of Diminishing Self-induction in B Circuit.

§ 66. A zigzag of wire was now prepared, consisting of the same length of the same wire as those round the room, wound zigzag on pegs on a board. A pair of wires were thus prepared, one of thin iron the other of thin copper. The thin copper wire round the rooms was still kept in the A circuit, and, in fact, everything else remained as it had been.

There was now, of course, no mutual induction between the parts of the circuit.

Alternative Path.	Length of B spark.
Thin iron zigzag	·97 centims.
Thin copper zigzag	·71 ,,

Substitute now in the A circuit the thin copper zigzag instead of the thin copper wire round room ; leave all else the same. (A spark still 3·5 centims.)

Alternative Path.	Length of B spark.
None	4·95 centims.
Thin iron zigzag.....	4·13 ,,

The diminution of L has brought up the length of the B spark tremendously.

Effect of the Light of One Spark in Assisting the Other.

§ 67. A large number of similar experiments were made, combining the zigzags with the wires round the room in various ways, and inserting other things in the A portion of the circuit ; but it is unnecessary to reproduce any more of these. As has been previously noticed (see §§ 43 and 45, Vol. XXII., p. 246), the adjustment of the maximum B spark was often found to be different when it could see the A spark from what it was when the light of the A spark was screened from it. The effect is not very large, and the conditions have to be such as give fair sensitiveness to the B spark—*i.e.*, those which make it neither very short nor very long ; but, under these conditions, the effect of the light of the A spark in assisting the passage of a discharge across the B spark-gap is quite distinct, even when the two sparks are not at all close to each other. The following extract indicates this :—

October 24th.—Spiral on lamp glass (§ 63) in A circuit, as shown in Fig. 11 of L and L_0 are interchanged. A spark length 3·5 as before.

The effect of the light of one spark in helping the other is plain enough in the above "thin copper wire round room ;" but it was repeated and verified with many other arrange-

Digitized by Google

ments. It had been previously observed in another manner by Hertz.

Alternative Path.	Condition as to Light.	Length of B spark.	Remarks concerning B spark.
None	Light of A screened off	7·0	...
„	Light of A visible at B	7·0	...
Thin Copper Wire round room	Light visible	2·775	9 sparks pass out of 10
„ „ „	„	2·800	5 „ „ 10
„ „ „	„	2·825	1 „ „ 10
„ „ „	Light screened off	2·675	6 „ „ 10

Experiment to compare Zigzags with Spirals of the same length.

§ 68. The same kind of wire as had been used for the zigzags (27 meters) was now wound on an open wooden frame in a spiral, say, a yard long and a foot square or thereabouts, with about an inch between the different turns.

The small spiral on lamp glass of § 63 was put in A circuit, and A spark adjusted to 3·5 centims. [Setting of A spark not precisely accurate from one day to another.] The following is a typical selection from the readings :—

Alternative Path.	Length of B spark.	——
None	7·93	
Thin copper zigzag	1·70	
Thin iron zigzag	1·88	
Thin iron spiral	3·36	
Thin copper spiral	4·03	but overflows jar nearly every time.
Both zigzags in series	2·2	

Thus, the effect of increasing L_0 on the length of B spark, everything else remaining the same, is very marked. The figures show that either spiral offers far more impedance than both the zigzags (of the same wire exactly) in series.

This is the end of the account of my experiments on "The Alternative Path."

MEMORANDUM ON THE PREPARATION OF THE CLARK'S STANDARD CELL.

The following draft memorandum has been drawn up for the consideration of the Electrical Standards Committee of the Board of Trade :—

Definition of the Cell.

The cell consists of zinc and mercury in a saturated solution of zinc sulphate and mercurous sulphate in water, prepared with mercurous sulphate in excess, and is conveniently contained in a cylindrical glass vessel.

Preparation of the Materials.

1. *The Mercury.*—To secure purity it should be first treated with acid in the usual manner, and subsequently distilled in vacuo.

2. *The Zinc.*—Take a portion of a rod of pure zinc, solder to one end a piece of copper wire, clean the whole with glass paper, carefully removing any loose pieces of the zinc. Just before making up the cell dip the zinc into dilute sulphuric acid, wash with distilled water, and dry with a clean cloth or filter paper.

3. *The Zinc Sulphate Solution.*—Prepare a saturated solution of pure ("pure re-crystallised") zinc sulphate by mixing in a flask distilled water with about twice its weight of crystals of pure zinc sulphate, and adding a little zinc carbonate to neutralise any free acid. The whole of the crystals should be dissolved with the aid of gentle heat, and the solution filtered, while still warm, into a stock bottle. Crystals will form as it cools, and when the solution is to be used a little should be taken from the bottom of the bottle near the crystals with a pipette. While this is being done the liquid should be at a decidedly higher temperature than that at which the cells will ordinarily be used.

4. *The Mercurous Sulphate.*—Take mercurous sulphate, purchased as pure, and wash it with distilled water. Drain off as much of the water as possible. Mix the washed mercurous sulphate in a mortar with the zinc sulphate solution, adding sufficient crystals of zinc sulphate from the stock bottle, to ensure saturation, and a small quantity of pure mercury. Mix these well together to form a paste of the consistence of cream, and then heat the paste sufficiently to dissolve the crystals, afterwards allowing the mixture to cool, and thus to form a saturated solution of mercurous sulphate in a saturated solution of zinc sulphate.* The presence of the free mercury through out the paste preserves the basicity of the salt, and is of the utmost importance.

Contact is made with the mercury by means of a platinum wire about No. 22 gauge. This is protected from contact with the other materials of the cell by being sealed into a glass tube. The ends of the wire project from the ends of the tube ; to one end a piece of copper wire is soldered, the other end and a portion of the glass tube dip into the mercury.

To set up the Cell.

The cell may conveniently be set up in a small test tube of about 2cm. diameter, and 6 or 7cm. deep. Place the mercury in the bottom of this tube, filling it to a depth of, say, 1·5cm. Cut a cork about ·5cm. thick to fit the tube ; at one side of the cork bore a hole through which the zinc rod can pass tightly ; at the other side bore another hole for the glass tube which covers the platinum wire ; at the edge of the cork cut a nick through which the air can pass when the cork is pushed into the tube. Pass the zinc rod about 1cm. through the cork.

Clean the glass tube and platinum wire carefully, then heat the exposed end of the platinum red hot, and insert it in the mercury in the test tube, taking care that the whole of the exposed platinum is covered.

Shake up the paste and introduce it without contact with the upper part of the walls of the test tube, filling the tube above the mercury to a depth of rather more than 2cm.†

Then insert the cork and zinc rod, passing the glass tube through the hole prepared for it. Push the cork gently down until its lower surface is nearly in contact with the liquid. The air will thus be nearly all expelled, and the cell will be ready for sealing.

Melt some marine glue until it is fluid enough to pour by its own weight, and pour it into the test tube above the cork, using sufficient to cover completely the zinc and soldering. The glass tube should project above the top of the marine glue.

The cell thus set up may be mounted in any desirable manner. It is convenient to arrange the mounting so that the cell may be immersed in a water bath up to the level of, say, the upper surface of the cork. Its temperature can then be determined more accurately than is possible when the cell is in air.

* Note.—If the saturated solution of zinc sulphate is not heated, the cells do not usually agree with each other until some time after they have been set up. If the above method is followed, the agreement is good at the time of setting up, and should be very close indeed after a day's rest. Care, however, must be taken that the paste is not super-saturated when cold.

† When the cell has been set up for a little time the more solid portion of the paste sinks to the bottom leaving clear liquid above.

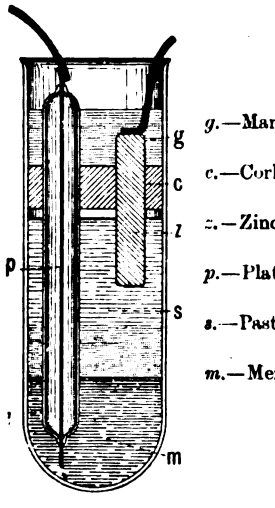
This figure, which does not form part of the memorandum, has been prepared in accordance with the particulars given therein.



PROF. EWING'S THEORY OF MAGNETISM.*

BY ARTHUR HOOPES.

The "Theory of Induced Magnetism" which Prof. Ewing published in the *Phil. Mag.* for September, 1890, is at once so beautifully simple and comprehensive that we have thought that some magnetisation curves actually obtained from the model which he suggests might be interesting as testing, in some degree, the efficiency of the hypothesis. With this end in view the accompanying curves were determined by the writer, under the direction of Dr. Henry Crew, of Haverford College.

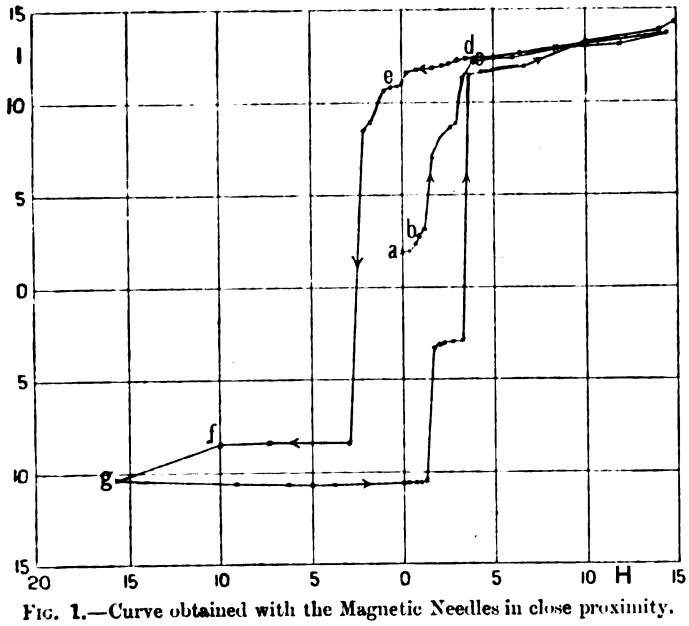


FIG. 1.—Curve obtained with the Magnetic Needles in close proximity.

The magnets used were similar to those described by Prof. Ewing, about 2in. long and balanced on sewing needles set in lead bases. They were 68 in number, and were placed in three layers or tiers on glass plates, which slipped into the magnetising coil. The coil was 32in. and 12in. in diameter, and was wound from end to end with 76 turns of wire. It was set with its axis east and west. The magnetic moment of the model was measured by a magnetometer 34in. from the middle of the coil. To eliminate the magnetic effect of the current in the coil, an opposing coil was adjusted on the other side of the magnetometer at such a distance that it just balanced the large coil when the magnets were out. The maximum strength of field used was about 2·7 C.G.S. units, or 15 times the horizontal component of the earth's field.

The method of obtaining the curves was simply to put in the magnets, stir them up and let them come to rest by themselves, then to vary the magnetising current through a cycle and read he magnetometer deflections at intervals. As no attempt was made to get anything but the *shape* of the curves, the tangents of the magnetometer and galvanometer deflections were plotted on a convenient scale, without regard to the absolute values of current and magnetic moment.

Figs. 1 and 2 show curves obtained with the magnets as close together as they could be placed without striking. They illustrate well the different results that may be caused by different initial directions of the magnets. The magnet *centres* were in almost the same positions in the two cases, but in Fig. 1 the magnets took the directions shown in Fig. 3, while for the curve of Fig. 2 the original state is shown by Fig. 4. Both curves show beautifully the small

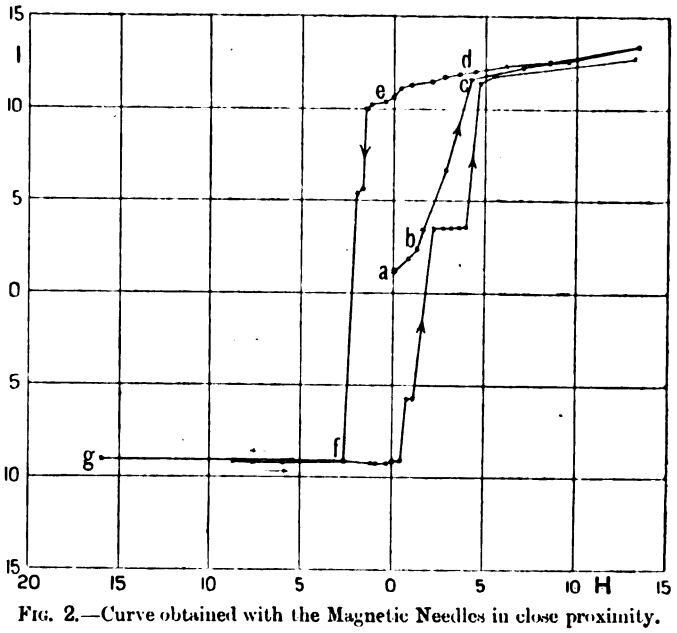

FIG. 2.—Curve obtained with the Magnetic Needles in close proximity.

susceptibility at first (*a* to *b*, Figs. 1 and 2), where the magnets are deflected through small angles, but have not yet passed through an unstable position. From *b* to *c* the magnets turned rapidly with small increase of current, and from *c* to the right they were brought more and more nearly into the direction of the axis of the coil, giving the flat part of the curve. On decreasing the current the curves almost retrace themselves to the point *d* directly above *c*, where stability begins. But here it leaves the ascending branch, because it takes less strength of field to *hold* them in this position than it required to

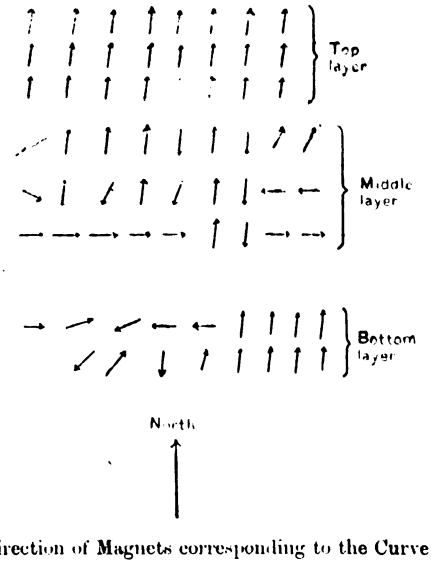

FIG. 3.—Direction of Magnets corresponding to the Curve in Fig. 1.

put them there. This state continues until the field is nearly zero strength, when two or three magnets turn, giving the small drop at *e*. A slight negative increase turns many more, and another reverses every remaining magnet except four, which are almost exactly opposite to the direction of the field. In Fig. 1 the increase from *f* to *g* turned these four, but in Fig. 2 they were not affected by the strongest current that could be used. Consequently the curve of Fig. 2 is almost horizontal between *f* and *g*. The differ

* From the *Electrical World* of New York.

Digitized by Google

ence was probably due to a slight change in the position of the plate which supported these magnets. Completing the cycle, the upward branch of Fig. 1 is seen to consist of two main steps, while Fig. 2 has three, and both curves are to the right of the origin.

These curves may possibly represent one group of molecules in a steel bar. Since the mean density of steel is nearly the same as that of iron, it appears that the large hysteresis of the former is due to the molecules in individual groups being nearer, the groups themselves being further apart than in soft iron. To diminish the hysteresis of the model, the magnets must be placed further apart, in order to lessen the stability of their positions. The area of the curve can thus be decreased indefinitely. The curve of Fig. 5 was taken with the magnet centres 2½in. apart—that is, with

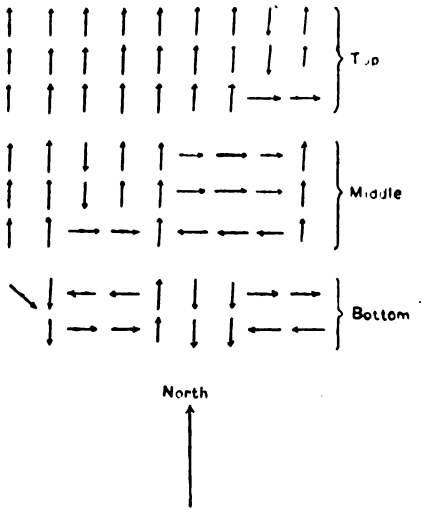

Fig. 4.—Direction of Magnets corresponding to the Curve in Fig. 2.

the magnet ends ½in. apart at the closest. In this curve the cycle was performed in the opposite direction to that of the others. The last downward branch is dotted to distinguish it from the first. The area of the curve suggests at once that if Figs. 1 and 2 represent the case of steel, Fig. 5 represents soft iron—that is, the case in which there is a less intimate connection of the molecules in their respective groups.

At *b* a small cycle* was superposed upon the main cycle, as shown by the small loop. At *c* the loop returns to the main curve. If one of these minor cycles be performed at a point like *d*, which represents a stable position of the magnets, the curve merely retraces itself, illustrating the fact that there is no hysteresis without

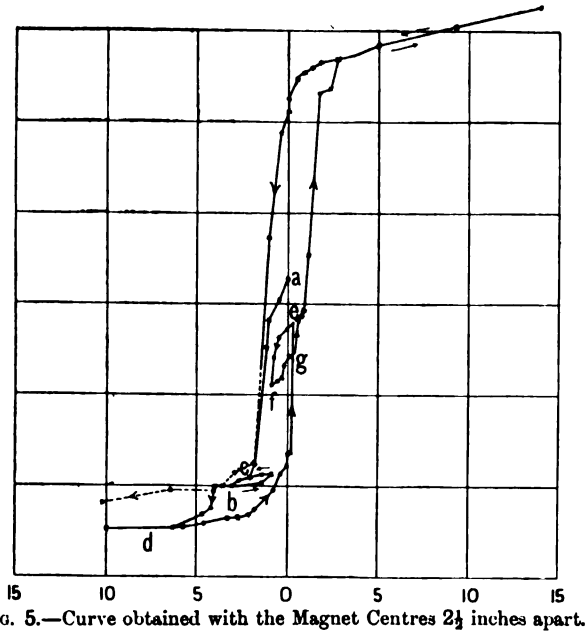

Fig. 5.—Curve obtained with the Magnet Centres 2½ inches apart.

passing through a position of instability. On the contrary, at a point like *e*, where nearly half of the magnets have just turned, the area is very large. It is interesting to note that the curve took a new track at *g* instead of returning to *e*.

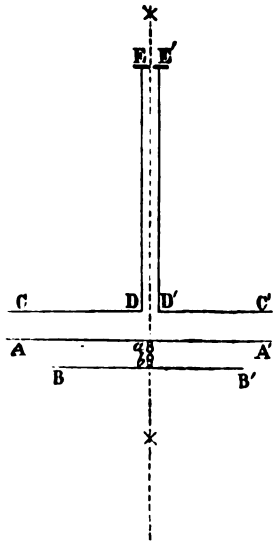
* Lord Rayleigh, *Phil. Mag.* March 1887

These are a few of the curves which have already been obtained from the model. They are necessarily very imperfect, largely on account of the relatively small number of magnets used. They suffice to show, however, the close resemblance of the model to actual magnetic metal, as far as the most important properties are concerned, which was all that was originally expected

ON THE DETERMINATION OF THE DIELECTRIC CONSTANT OF GLASS BY THE AID OF VERY RAPID ELECTRICAL OSCILLATIONS.*

BY R. BLONDLOT.

Very rapid electrical oscillations, such as those produced by Hertz's apparatus, have been used by J. J. Thomson for the determination of dielectric constants.† J. J. Thomson draws the following conclusion from his experiments:—"With oscillations of the order of 25,000,000 per second, the specific inductive capacity of glass is nearly equal to the square of its index of refraction, and is considerably less than it is for slower reversals." It may be objected to this conclusion that a formula is employed involving the period of the oscillations, and that the accuracy of the formula is doubtful in the case of very rapid oscillations. E. Lecher has determined the dielectric constants of several substances by means of a method also based on the determination of the wave length of very rapid



oscillations, but without using any formula. The conclusions of Lecher are diametrically opposed to those of J. J. Thomson. He remarks, "not only does the dielectric constant determined by aid of the capacity not become smaller for very rapid oscillations, but it even notably increases." These contradictory conclusions induced me to investigate the matter. The method which I used is based upon the employment of very rapid oscillations, but does not involve any formula.

A large rectangular brass plate, A A′, is fixed vertically, and a second smaller plate, B B′, forms a condenser with the first. This condenser can discharge itself by means of the poles *a b*; *a* being in communication with the gas tubes and *b* with one of the poles of an induction coil, the other pole of which communicates with the gas tubes. When the induction coil is at work the condenser A B is the seat of oscillatory charges and discharges, the period of which is of the order of $\frac{1}{100000000}$ of a second. We thus have in the space situated on the side of A A′ opposite to B B′ a periodic electromagnetic field which (and this is the important point) has X X as its plane of symmetry. Two square plates, C D and C′ D′, were fixed parallel to A A′, and symmetrically with regard to X X, and at the points D D′, two wires were soldered, terminating at E and E′ in two electric light carbon pencils arranged opposite to one another in close proximity.

When the coil is set in operation no glow is to be seen between E and E′. This is due to the symmetry of the apparatus. If we now interpose between A A and C D a sheet of glass, sparking immediately takes place between E and E′. This is due to the fact that the induction received by C D is stronger than that received by C′ D′. If we now place a sheet of sulphur between A A and C′ D′,

* *Comptes Rendus*, Vol. CXII, No. 19. † *See* Proc. Roy. Soc., June, 1889.

Digitized by Google

and if we give it a thickness such that the inductive action on C′ D′ is equal to the inductive action on C D, the sparking between E and E′ ceases. Reciprocally the disappearance of sparking at E E′ ndicates that the inductions transmitted to C D and C′ D′ are equal. It suffices, therefore, to measure the thickness of the dielectric to determine by an easy calculation the ratio of the dielectric constants of glass and sulphur. Thanks to experimental precautions, which I cannot describe here, I was able to render this method sensitive and precise.

The plate of glass which I employed was exactly 3cm. thick. I melted two sheets of sulphur in the form of prisms of the same angle, so that in placing them side by side, as in the Babinet compensator, a sheet with parallel faces is formed, the thickness of which can be varied. I found 3·15cm. to be the thickness of the sheet of sulphur, exactly compensating the sheet of glass. To complete the determination of the dielectric constant of glass, it was necessary to know that of sulphur. This was easy, since sulphur is an almost perfect dielectric. I employed the method described by J. Curie,* and I found the number to be 2·94, and from this deduced the dielectric constant of glass to be $2·8 (=1·67)^2$.

This result one can see is nearly identical with that of J. J. Thomson. Maxwell's law is not verified exactly, since the mean index of refraction of my glass sheet was about 1 51, but the discrepancy is a great deal less than that observable in the value of the dielectric constant obtained by slower methods. My conclusion is the same as that of J. J. Thomson.

TELEGRAPHIC AND TELEPHONIC CABLES IN THE ST. GOTHARD TUNNEL.†

As soon as the St. Gothard Tunnel was complete, the telegraphic administration laid, during the winter of 1881-82, a seven-core cable for the telegraphic service of the State and the Railway Company. In addition, a single wire cable was laid for use in connection with the signal boxes installed at the 14 kilometric stations in the tunnel. The cables were made by Felten and Guillaume, of Mulheim, and each of the cores consisted of seven wires, ·7mm. in diameter, and insulated by four coatings of gutta-percha and Chatterton compound, having then a diameter of 5 2mm. The whole was then wound with tarred hemp, armed with a covering of galvanised iron wire, and finally covered with a coating of jute having a thickness of 3mm. After a survey of the tunnel, the cable was placed in an iron trough, fixed to the wall of the tunnel at a height of 2·4 metres above the permanent way, the trough being enclosed in a creosoted wood casing. In spite of the excellent quality of the cables, and the care with which they were laid, serious defects soon came to light, the insulation of 3,000 megohms per kilometre descending at times to five megohms and frequent disturbances of the service resulted. A careful investigation of the situation showed what were the causes of this abnormal state of the cables, causes which, although present in all tunnels of any size, seem sufficiently interesting to warrant careful analysis.

The water which filters into the tunnel is very abundant, amounting to nearly 300 litres per second (66 gallons per second, or 5,700,000 gallons per day). It may be interesting to observe, in passing, that at the entrance of the tunnel this water feeds a fall of 15 metres, which works a turbine driving the two dynamos supplying light to the station and village of Airolo.

The firm of Siemens and Halske, the contractors for the new cable, analysed 150 bottles of infiltration water taken from various places in the tunnel. Several of the samples contained considerable quantities of sulphuretted hydrogen. Moreover, an examination of the stagnant water in the trough showed that it contained all the ingredients favourable to a rapid corrosion of the protective covering of the cable; ingredients produced by the incomplete combustion of the coal of the locomotives in an atmosphere almost denuded of oxygen. The products of combustion, it may be added, have had a very marked effect on the permanent way. These analyses showed the danger of placing cables in a trough arranged along the sides of the wall, and pointed to the conclusion that the best way would be to place the cables under ground in a bed of sand, so as protect them from the destructive action of the water and the atmosphere of the tunnel. It was evident that care must be taken in tapping and diverting the springs, which rise from the soil at several points in the tunnel, all the more so because these springs were slightly sulphurous. Prudence also demanded that the cable should be covered with a completely impermeable coat of lead, the whole being protected with solid stone slabs.

The railway company, therefore, ordered two cables from Messrs. Siemens and Halse, the data of which were determined by traffic exigences, as well as by the considerations referred to above. One cable was intended for telegraphic purposes, and had three cores; the second cable was a concentric telephone line. The following are the data of these two cables:—

Each wire of the telegraph cable was of pure copper, and was 1·38mm. in diameter, covered with three layers of jute to a total diameter of 4·4mm., and enclosed in a lead covering 1·3mm. thick. The three wires were then bound together, and the whole enclosed in a covering of paper and asphalt, which, in its turn, was protected by a sheath formed of 20 galvanised iron wires 3·75mm. in diameter, the external diameter of the cable being 33mm.

The following are the electrical constants per kilometre, at 16°C.:—

Resistance	11·5 to 12 ohms.
Insulation	500 megohms.
Capacity	·25 microfarad.

The telephone cable had an interior core, consisting of a single wire 1mm. in diameter, wound with jute to a diameter of 2·5mm. This was then surrounded by a layer of seven wires each ·4mm. in diameter, and metallically united to each other by tin-foil. The whole was then wound with strands of jute (4·4mm. in diameter), and enclosed in a lead covering 1·3mm. thick, the external diameter of the whole being 7mm. This was, in turn, protected by a layer of paper and asphalt, a sheath of 16 galvanised iron wires coming next, a final protective coating, having an asphalt base, being then put on. The constants are as follows at 15°C.:—

External diameter	24 mm.
Resistance per kilometre	·25 ohms.
Insulation	250 megohms.
Capacity	·31 microfarad.

This telephone cable was joined up to the fourteen telephonic posts in the tunnel, and to the stations at either end.

In laying the cable, a trench 50 to 80cm. deep was excavated; at the bottom there was a layer of gravel 10cm. thick, then came a layer of sand 10cm. thick, then the cables, then a layer of sand 20cm. thick, then a granite slab, and finally gravel. The work of laying occupied two whole months, namely, from September 15th to the middle of November of last year, work being only possible at night time, during the train intervals. To the many difficulties encountered must be added the pestiferous atmosphere of the tunnel, and the violent wind from north to south, which always blows in the tunnel. The work required 500 loads of sand, 250 of slabs, 32 of cables, and 500 of excavated earth.

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements should be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday.*

SMALL PREPAID ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1891 Edition, published on the 23rd February, 1891, consists of 900 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with well-written Biographical Notices of leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1891 should be ordered at once. Price 5s., post free 5s. 9d. Abroad postage extra. Prospectuses free.

ELECTRICAL BOOKS AND PUBLICATIONS

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad*

"THE ELECTRICIAN" *Series at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING. Vol. I. Price 7s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

STEEL-PLATE PORTRAITS

Of W. H. Preece, F.R.S.; Michael Faraday; Sir John Pender, K.C.M.G.; Sir William Thomson, F.R.S. (Past-President of the Institution of Electrical Engineers); C. H. B. Patey, C.B. (Late Secretary of Telegraphs, G.P.O.); Dr. John Hopkinson, F.R.S. (Past-President of the Institution of Electrical Engineers); Dr. Oliver J. Lodge, F.R.S., and Prof. William Crookes, F.R.S. (President of the Institution of Electrical Engineers), have been issued as Supplements to "THE ELECTRICIAN." *A few Copies of these admirably-executed Steel Engravings can be supplied, price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price, post free, 4s. 6d.*

POPULAR SCIENCE.

The widespread interest in popular science which is exemplified in the numerous books, journals, and lectures of the day, dates back only about half a century, and was probably due in a large degree to the charm of Faraday's discourses. The exact period at which it first arose is impossible to define, if only because the diversion of to-day was the erudition of our ancestors. From the accounts, and indeed the official records, of the transactions of the Royal Society in its early beginnings, it appears that its members often busied themselves about matters that would now seem very trifling to any well-informed person. But while such dilettanti as SAMUEL PEPYS were in a prominent position among the followers of science, it was then, as now, difficult to draw the line between men who are merely interested in the results of science and those who follow it as a pursuit, whether professionally or no. The books which deal with popular science might be considered as introductory to its proper understanding, and indeed many of us owe much to Prof. PEPPER and others; but the crowded theatre of the Royal Institution on Friday evenings, to say nothing of the other meetings both there and elsewhere, show that the intelligent and well-educated public take a keen interest in a good scientific lecture as an end in itself, and not as the commencement of a scientific education.

Digitized by Google

The questions sometimes arise, What good does it do them, how much do they understand? and how much will they carry away with them? These questions should be commended rather to the consideration of the teachers than to their hearers. A well-known name or a neat title will draw the audience. The man need never have lectured before if only he is well enough known; he will draw, at least, once.

If the lecturer treats his subject skilfully, the listener finds it easier and more congenial to take in a little diluted science in this way, than by spending the same amount of time over a book. Even if the ideas gathered by the audience are few and indefinite, the essence of the matter may still have been imparted, for it may be safely asserted that a person who attends a number of independent lectures gradually acquires the power of following them. The desirable thing to spread among the people is not so much the knowledge of facts, as the education of the scientific faculties. This can only be done on a large scale by arresting the attention by lecturing, since few people take sufficient interest to acquire science for themselves. Books are dead things, but the popular lecturer can impart a vivid interest to his subject which can be obtained in no other way.

Popular science naturally divides itself into two kinds, the one can be readily appreciated by the public, and the other is dished up in such a shape that it appears pretty and amusing. The first is to be found in our lecture-rooms, and the second in French illustrated books—we cannot say literature. So long as science is not distorted in the endeavour to make it interesting, or forced into playing tricks unworthy of a good conjuror, facts which have a practical bearing on modern life, or which have a beauty of their own, are worth illustrating. In almost any man's work there are fragments which can be assimilated by anybody of intelligence, though the bulk of it may be very hard to digest. The theory of electric images is to be found in mathematical treatises and rarely elsewhere, but Sir William Thomson treated it experimentally in such a manner on a recent occasion, that no one who then became acquainted with the subject for the first time could have thought that it was even a subject for a mathematician to deal with. While there are many difficulties in the way of the teacher, whose endeavour must always be to suppress complications, and who is compelled to conventionalise at the expense sometimes of accuracy, the listeners are often rather bothered with the discovery of their own ignorance, are impatient of details, and are often on the verge of being bored. No doubt the true method of learning a science is to begin at the elements, and having mastered the principles, to study the phenomena in the light of these principles, just as languages are taught on a foundation of grammar. But it is generally conceded that grammar is a matter of discipline, a form of mental exercise useful for young minds, rather than an efficient means of learning a language; nor can the grammar of a tongue be fully appreciated until considerable progress has been made. No schoolmaster with a proper respect for the traditions of his trade will admit this, of course; and with the same instinctive feeling some men think that the pearls of knowledge which have been purchased at the price of hard study must not be cast before the swine of a fashionable audience. But this is mere selfishness.

If electrical science is to be studied by first mastering the principles, what are these principles, and who has mastered them? Are not the foremost thinkers of the day engaged in attempting to penetrate the threshold of these principles, and are not the elementary facts among the hardest to thoroughly understand? A good deal of the so-called popular science of to-day consists in the display of brilliant experiments, and the interest which the intelligent public take in witnessing experiments which they cannot possibly understand is somewhat remarkable. Sometimes their admiration is evoked by the admirable dexterity and manipulation of the lecturer, and often has Prof. Tyndall held his audience in breathless suspense, or has entranced them with the real beauty of his skill, and it is largely to him that we owe this system of education by the eye. The chain of silver links and platinum cannot but convey the lesson that substances differ in their specific resistance, even if the careless hearer forgets which metal glowed and which remained cool. Occasionally the object lesson becomes all object and no lesson, and, as in demonstrations of polarised light, the lecturer is justified after a time in giving up any attempt to explain the technique of the pictures painted indeed by Nature, but in colours which appear only at the command of Science.

The object of pure science is to trace out truth, while applied science appeals to the pocket; but popular science endeavours to place truth in a pleasing form. It is an art which, like music, appeals to our senses, and it is often remarkable how much more we are interested in some application of a simple fact, than in the study of a natural law of much greater consequence. The faults of the eye, and the character of vision, are not very attractive subjects in themselves, but when skillfully made use of, as in the stereoscope, to produce a pleasing illusion, we are at once interested. A simple and clever improvement of this instrument is due to Mr. Schobben, and depends upon the well-known fact that pieces of red and green glass can be found, each of which is opaque to the light which passes through the other. When two stereoscopic pictures are projected on a screen by means of a double lantern shining through red and green glass, and the coloured images so formed are viewed through a pair of spectacles, the glasses of which are also red and green, each eye can perceive but one of the images through the glass in front of it, and all the appearance of solidity is obtained. The effect of converting the two dimensioned pictures into a solid landscape is so startling that one is at first inclined to think that the problem of the fourth dimension is reduced to finding an appropriate pair of spectacles. When this brilliant example of popular science was exhibited by Mr. Woodward at the Physical Society, on Friday last, the intense interest evinced in it by the grave and reverend seigneurs of the Society only showed how universally the popular element influences our appreciation of science.

ELECTRIC AND MAGNETIC THEORIES.

BY SILVANUS P. THOMPSON, D.SC.

(*Continued from page 65.*)

§ 11. We have next to consider the question of steady current flow. In this case there is not, so far as I am aware, any direct experimental proof that the energy furnished by the source is transferred by the external medium to that part of the circuit, when it is to be utilised or transformed into heat, light, or work. On the other hand, there is nothing in the way of experiment to support the notion that the energy is transmitted by an end thrust along the wire of the circuit. In the absence, therefore, of any direct proof either way, it is only logical to assume that the mode in which the energy is transferred is the same as in those cases previously considered, in which it was proved, by direct experiment, that energy was transferred across the medium. In the case of steady currents, so long as they are really steady, we have no evidence whatever of propagation of the action from point to point, either inside or outside the conductive circuit; nothing to give us

Digitized by Google

the slightest information as to either the rate or the direction of the propagation of the action. The chemical evidence as to the propagation of current is quite compatible with the theory that the current flows from positive to negative, or with the theory that it flows in the reverse direction, or with the theory that there are two currents simultaneously flowing in opposite directions; and any theory which merely takes into account the flow of current and neglects the distribution of electric potential is obviously incompetent to deal with the question how the energy is propagated.

In the absence of direct proofs either way, I shall therefore content myself with a few descriptive paragraphs as to the propagation of energy, on the hypothesis that in the case of steady flow the energy is transferred across the dielectric medium, as it is in the case of variable currents.

§ 12. Consider, then, a circuit made up of a row of battery-cells AA′ acting as the source, and of some wires which are in part thick, but contain a thin piece B B′, which will become hot (Fig. 6). Accepting the hypothesis that the energy travels across the medium, the energy paths will be comparatively short; shorter than if it were supposed that the energy had to travel around the thick conducting wires at the ends. In reality, such energy paths will form a series of curvilinear tracks, after the fashion of the end view shown in Fig. 7, where A is a section of one of the battery-cells, and B that of the corresponding part of the thin wire. The energy starts off from the surface of the zinc plates, flowing outwards into space, and, swirling round, concentrates itself in exactly the amount necessary to keep up the heating effect at the point in question.

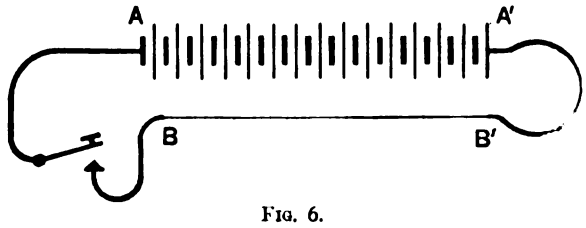

Fig. 6.

Again, consider Fig. 8. Here, a battery of seven cells, having small internal resistance, is connected to a thin wire which bends round from the positive pole P to the negative pole N. Let us assume, for the sake of simplification, that these cells have an electromotive force of one volt each. Let us apply a proper voltmeter, a quadrant electrometer, let us say,

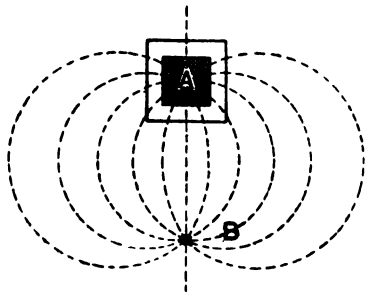

Fig. 7.

to measure the variations of potential. If one pole of the electrometer be connected to the negative terminal N, and connection be made successively from the other pole to various points along the row of cells, we shall observe 1 volt at the end of the first cell, 2 volts at the end of the second, and so on up to 7 volts at P. If we then go exploring in the same way along the wire we shall find that, beginning at N, there will be a certain point a little way along the circuit, marked 1, where the potential is 1 volt, further on 2 volts, and so on, ending with 7 volts at P. There will then be in this system two points at which the potential has the same values, one point in the row of cells, another point in the wire. But besides these two points in the conductive system there will be others in the surrounding space. For example, in the space surrounding the wire near the point marked 3, the potential will have a value of nearly 3 volts, and the dotted line drawn from 3 on the wire to 3 in the row of cells is intended to indicate the general position of such points of equal potential. In the same way, the dotted line 4, 4, marks the equipotential line, or rather surface, of four volts. It must be remembered that the equipotential surfaces will emerge from the battery normally all round, and will intersect the external circuit, also normally. The swirling lines of Fig. 7 would all lie in one equipotential surface. In the above statement it has been assumed that there is no chemical difference of potential between the metal and the medium to complicate matters by a difference of potential at the surface. One only needs to suppose the ordinary air to be replaced by nitrogen or other chemically inert material to realise the case. By purely mathematical reasoning, quite apart from the argument which I have put forward as to logical inference from the known cases to the unknown ones, Poynting and Heaviside inferred that the transfer of energy must take place in paths parallel to the surfaces of electric equipotential. The meaning of that proposition in relation to Fig. 8 is that the energy given out by each cell finds its way across the medium to the corresponding part of the external circuit. For example, the energy due to the combustion of zinc in cell No. 2, between points 1 and 2 in the row of cells, will go across the medium to supply the waste of energy that is being dissipated as heat between the points 1 and 2 of the wire; and the energy paths emerging out of this cell will consequently be limited by the dotted lines 1, 1, and 2, 2.

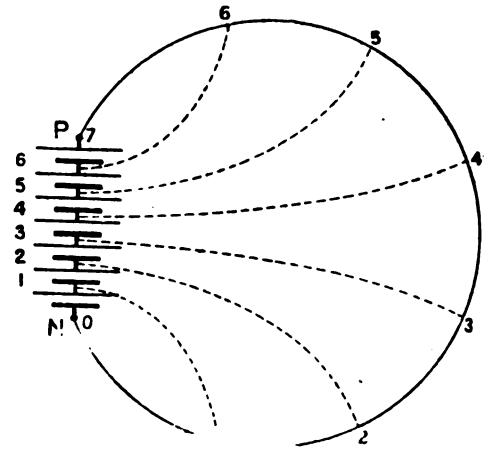

Fig. 8.

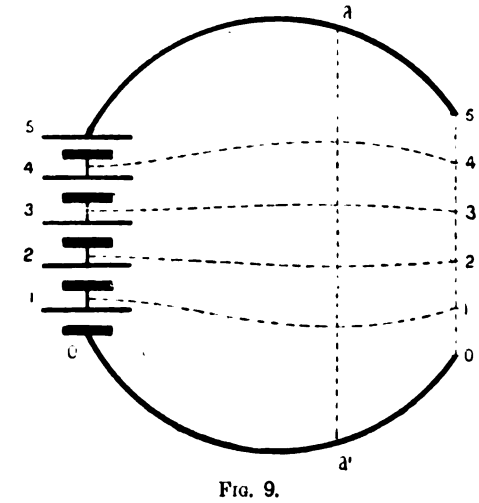

Fig. 9.

Fig. 9 is another variation of the same theme. Here are five cells, and the circuit is composed of two thick wires, with a thin piece interposed. If the cells are of small internal resistance, and of 1 volt apiece, the potential will rise from 0 to 5 volts, whether measured along the row of cells or along the wire. If one considers any line such as $a\,a'$ drawn across the circuit from one thick wire to the other, it is clear that between a and a' there is a difference of potential of 5 volts, and, as at

Digitized by Google

intermediate points the potential must have intermediate values, points corresponding to 1, 2, 3, and 4 volts can be found. These lie, of course, in the equipotential surfaces, which can be drawn across the system. Surely it is more rational to suppose that the energy which heats the piece of wire between 0 and 1 comes from the corrresponding cell, and that which heats the next piece of wire from 1 to 2 comes from the next cell, than to suppose that the energy which heats any particular piece of the wire comes from nowhere in particular. According to the hydraulic notions, the energy which is to heat the piece of wire, 0, 1, has to be forced along the wire through all the other pieces, and, instead of coming by the natural route across the medium, has to travel up the row of cells, across the top conducting piece, and then down the thin wire.

§ 13. In all these cases matters are somewhat complicated by the circumstance that in the form of circuit chosen the energy paths complex in form. We will, therefore, consider another circuit of different shape, so chosen that the energy paths will be simple. Imagine a sort of voltaic pile, made up of alternate pieces of zinc, copper, and moist conductor, these pieces being in the form of round discs with a central hole. When piled upon one another they will form a hollow column. Suppose the bottom to be closed by a plate of zinc and the top by a plate of copper, and a thin wire to be connected from the middle of the top plate to the middle of the bottom one. We shall then have a complete circuit constituted by the cylindrical battery outside and the wire inside. According to the

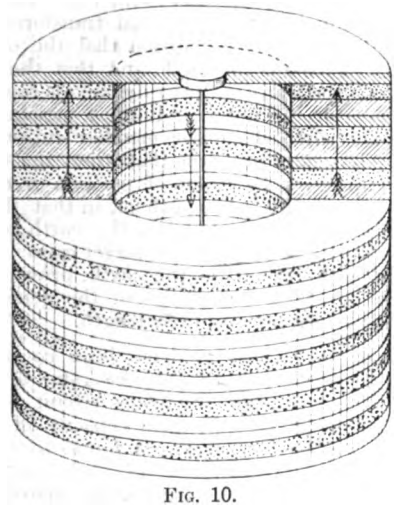

Fig. 10.

hydraulic hypothesis, there will be a current propelled up the cylindrical pile, across the top plate and down through the central wire, as in Fig. 10, and energy will travel by the same route, being pushed along the wire, and heating it as it goes. According to the modern and rational view, the energy which is set free at the surface where the zinc is attacked by the acid will simply flow radially inwards in all directions to the wire, just enough going to any given part of it to keep up the radiation of heat from that part. Fig. 11 gives a sectional view of the supposed arrangement. The energy paths being straight across from the cells to the wire, have not been drawn in as in some of the preceding figures.

§ 14. Before proceeding any further, I pause to consider some of the *à priori* objections raised by Mr. Sprague to the notion of energy paths through the medium.

In § 6, p. 514, Mr. Sprague says:—"That is the essential characteristic of electric energy, that it is linear, and controlled in direction as distinguished from the energy of heat and light, which are radiant, though even they can be to some extent controlled in direction." A most misleading statement. What is more certain than that in Hertz's experiments electric energy is radiant in precisely the same sense as light is radiant? And, again, in those cases where there is a steady flow of so-called current, is it always "linear and controlled in direction"? How about the spreading of currents in metal sheets, or through an earth return? I pass on to § 18, p. 576, where Mr. Sprague puts a few conundrums. He observes that, if the source, instead of sending energy into the conductor, sends it into the medium, "it follows that at every point of the circuit an amount of energy must enter the conductor sufficient to work the mechanism, be it what it may, which transmits, or is, the current." (So far, I quite agree.) "We have now to solve this problem: How does the current which does not exist attract from outside space the energy which is to produce the current and control the outside energy?" This is very nearly as wise a query as the following:—When a pull is transmitted along a chain, each link pulls at the next one; we have therefore to solve the problem, how does any one link, in which at first no pull exists, contrive to attract from the link next to it sufficient force to exert the required pull?

But Mr. Sprague proceeds:—"But the current is exactly equal at all parts. The energy needed is not equal at all parts" (I quite agree, and hold that this in itself is a ground for thinking that the path of the current is not the same as the path of the energy), "it increases in the same ratio as the capacity" (does he not mean conductance?) "of the conductor diminishes." "Problem: How does the external energy distinguish where much or little of it is wanted?" Again, I can parallel the query by one equally serviceable. The wheels of a watch do not turn at equal rates; how does each of them know how fast it is to turn? Or, again; when a river turns in a bend the water is found to run at different rates at the two sides. Problem: How does the energy needed by the water in getting up speed know where much or little of it is wanted?

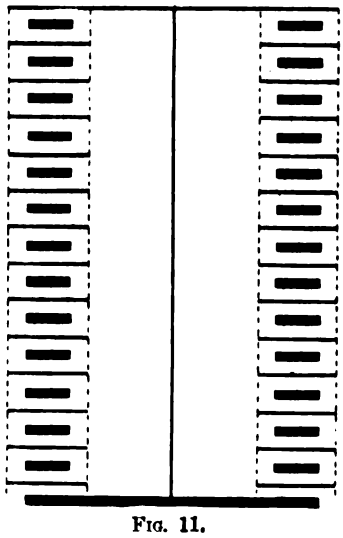

Fig. 11.

There is nothing either absurd or extraordinary in the energy proportioning itself to the requirements of the circuit; the thing that would be absurd or difficult to understand would be that the energy should not so proportion itself. Refer back to Fig. 9, and consider what would happen if one part of the thin wire should suddenly offer a greater resistance than the rest. Suppose this to happen with the piece between points 2 and 3. What would occur? Well, instantly the distribution of potential would alter itself, a fall of more than one volt occurring at this part, and a proportionately lesser fall along the other parts. As a consequence, the energy-paths would converge more densely upon this part, and less densely on the other part. To ask how the energy knows where it is wanted is simply trifling with the question.

(*To be continued.*)

THE LIGHTING OF THE CENTRAL STATION AND HOTEL, GLASGOW.

The Caledonian Central Station and Hotel, Glasgow, are now lit throughout by electricity. Brush arc lamps have, however, been running in the station for the past six years. These are of the ordinary 10 ampere type, and are suspended at a height of 16ft. above the platforms, and spaced 47ft. apart; the result being a very even and satisfactory distribution of light. The number of lamps employed over the platforms is 51, illuminating an area of 112,000 square feet; eight other lamps

Digitized by Google

are employed at the entrance to the station and in the yards, &c.

The hotel and station buildings have just been fitted throughout with incandescent lamps by Messrs. Mavor and Coulson, the work being carried out to the specification and under the superintendence of Mr. A. S. Dunn, telegraph superintendent, Caledonian Railway Company. There are 1,300 16 c.p. lamps in the hotel, and 400 in the station buildings, &c. The mains are carried in heavy casing, let into the wall of the luggage hoist. Each floor is fed by separate mains, and thus heavy T joints and main fuses are avoided in the building. The mains are brought into distributing boxes in the corridors, and are connected each with a copper bar of L section, which is mounted on a slate base. Facing the bar a number of short contact pieces of the same section as the bar are fixed, and to these pieces the ends of the distributing conductors are attached.

In the distributing box the connection between the bar and the contact pieces is made by means of a fuse mounted between two copper springs, which are attached to a porcelain block. The block is made to push tightly in between the bar and the contact, the copper springs pressing against them. Except in a few special cases, there are no other fuses on the branches to the lamps but those just described. The conductors leaving the fuse contacts are of 7/21½ cable, and this is carried right down to lamps and switches. Where flexible cord is used this is of 225/40's, so that in no case is a fuse necessary in the ceiling connections or switches. Six or eight lamps are supplied from each 7/21½ cable. In some cases the number of lamps at a considerable distance from the first distributing box is such that it would not have been convenient to run a sufficient number of 7/21½ branches to feed them. In these cases one or more pairs of fuse terminals are provided in the first distributing box, and a pair of suitable cables run from them to a second distributing box, whence the distribution is effected by means of 7/21½ cables. This system has been employed by Messrs. Mavor and Coulson since 1885, and it is now the general practice of the firm to use nothing smaller than 7/21½ cable, or the equivalent of No. 14 B.W.G., for switch and lamp connections.

A good effect and efficient illumination is produced under the railway bridge in Argyle-street. The portion of the street is 140ft. × 60ft., and nine 200 c.p. Sunbeam lamps are used with 18in. enamelled iron reflectors above them. The supports for these lamps are hung from spiral springs, to avoid possible breakage of filaments by the vibration produced by trains.

The generating plant occupies some of the arches upon which the station is built. Steam is taken from a range of Lancashire boilers, which also supply the laundry-heating apparatus, &c. The pressure is 50lb. in the square inch. The motive power consists of two single cylinder engines and one larger engine. The two smaller engines have been built by Messrs. Fullerton, Hodgart, and Barclay, engineers, Paisley. They are fitted with trip valve gear. The governor mechanism is disconnected from the valve gearing, and is free to adjust itself accurately to the load until the moment when the trigger engages with the motion rod. Its action is, therefore, undisturbed except by the unavoidable friction of its own working parts. The larger engine has been converted by the same firm, a similar trip gear and governor being employed to operate grid valves, working on the back of the ordinary slide valves, and at right angles to them. The arrangement gives complete satisfaction. Each of the three engines drives by band a separate section of shafting. The ends of the sections are fitted with couplings, but are left uncoupled under normal working conditions. The dynamos for the glow lamps are by Crompton and Co. There are two 38 kilowatt machines and one 20 kilowatt machine. The switch-board is arranged so that the engineers in charge is able to ascertain the current passing to any circuit, and to distribute the load among the dynamos as he may wish. Sir William Thomson's voltmeters and current gauges are employed. Switch-board, switches, &c., have been designed, and the whole of the work carried out under the supervision of Mr. W. B. Sayers, Messrs. Mavor and Coulson's manager.

ON SOME EFFECTS OF ALTERNATING-CURRENT FLOW IN CIRCUITS HAVING CAPACITY AND SELF-INDUCTION.*

BY DR. J. A. FLEMING.

(Concluded from page 77.)

22. Reference has been made recently in a Paper read by Major Cardew to the difference of electric condition as regards potential above the earth which will exist between two insulated conductors one of which entirely encloses the other, and which have different capacities, when they are connected to the terminals of an insulated transformer or alternator. In the case of a concentric cable the two copper members of which are insulated from each other, and the outer one insulated from a metallic sheath connected to earth, we have two insulated conductors, the interior one having capacity with reference to the outer, but not with reference to the earth, and the outer one having capacity both with reference to the inner and also with respect to the earth. This last capacity is generally, in cables as actually made, very much greater than the former.

In the case of the Ferranti trunk mains, the inner-to-outer capacity is, as we have seen, about one-third of a microfarad per mile run of the cable. Calculating from the measured dimensions, and from the specific inductive capacity of the insulating material as deduced from the inner-to-outer capacity, the magnitude of the outer-to-earth capacity I find to be about ten times greater, or more than three microfarads per mile. It follows immediately, from elementary principles, that the two insulated members of such a concentric cable will, when connected respectively to the terminals of an insulated transformer or dynamo, always be brought into such a condition that the outer member is at zero-potential as regards the earth, and that the full difference of potential which the transformer or dynamo is capable of making will subsist between the outer and inner member of the cable. This is true only when the outer member entirely encloses the inner member; but it is also true that when the two conductors have different capacities, by reason of position or form, there will be an electrical inequality between them, in that the difference of potential between each conductor and the earth will not be the same. The conductor which has the larger capacity will have the lesser potential with respect to the earth, provided always that both conductors attached to the poles of the generator or transformer are insulated throughout their length.

23. The condenser effect we have been considering, and in particular the alteration of the change ratio of a transformer which takes place when its secondary circuit is connected to a conductor system having a certain capacity in relation to the inductance of that secondary circuit, is found to operate in many curious ways in the practical use of such combinations. For instance, if a pair of alternators separately excited are working in parallel on an omnibus main leading to a conductor system of no sensible capacity, then we know very well that if the dynamos are synchronised, and contributing equally to the outgoing current, the method adopted to take one dynamo out of circuit would be to lower its exciting current, and when its outgoing current fell to zero to sever its connection with the omnibus main. If, however, the alternators are working through step-up transformers, and into a conductor system consisting of concentric cable, it is found by experience that the exciting current of the dynamo to be taken out must be raised, and not lowered, in order to bring it into a condition in which it can be cut off from the omnibus main without dangerous sparking at the switch; and, conversely, in putting it into parallel the incoming alternator has to be excited to a lower electromotive force than is necessary to maintain the standard potential difference at the terminals of the step-up transformer before putting it into connection with the omnibus main. This is obviously due to the fact that the change ratio of the step-up transformer is altered by the very act of putting it into connection with the conductor system, and hence the excitation of the alternator at the moment of making or breaking connection with the main must be such as will bring the potential difference of the free secondary terminals of the step-up transformer to a value equal to the potential difference of the two points on the conductor having capacity to which they are about to be connected, or from which they have just been severed; and when the connection of the alternator is made, the excitation can be altered to divide the load on the machines properly. This, of course, would not be case if high-tension alternators of very small inductance were set to work in parallel on such a concentric conductor system. In this case the condenser effect is practically nothing, and the behaviour of the machines on going into or out of parallel would present nothing unusual.

24. In the cases briefly discussed above, the cables, whether concentric or simple, have been found to act as single condensers substituted for them would act; and in the experiments described no progressive rise of pressure from one end to the other of a cable possessing capacity was found to exist.

It is, however, quite possible for self-induction, resistance, and capacity to be so combined together in one conductor that the action of an impressed periodic electromotive force at one end will create a progressive rise of mean pressure along the cable when the far end is insulated. The complete theory of such effect is rather too long to discuss here. The propagation of a simple periodic current and the action of a simple periodic electromotive force upon a concentric cable has been very fully discussed by Mr. Oliver Heaviside in an able series of papers on "The Self-Induction of Wires," published in the *Philosophical Magazine* for 1886 and 1887. A very brief summary of the results is all that can be given here; but those desirous of further information may be particularly referred to *Philosophical Magazine*, Vol. XXIII., January, 1887, page 18, in which paper Mr. Heaviside deals with the problem which is particularly the practical one — viz., a concentric cable having at one end a transmitting apparatus, such as a telephone, alternator, or a step-up transformer, and at the other a receiving instrument, such as another telephone or a step-down transformer.

We have, then, a sending instrument having resistance and inductance; a cable having resistance, capacity, and inductance; and a receiver having also resistance and inductance. Given the electromotive force in the transmitter, the problem is to find the current in the receiver.

Consider, first, a very long concentric cable having inductance L, resistance R, and capacity C, all per unit of length. Fix attention upon a small length of the cable, δx, and suppose that the current flowing into this element at any instant is i, and the current flowing out of it is $i - \delta i$ when some electromotive force acts at one end of the cable. Also, let v be the potential of the inner conductor at the one end of the element of length, δx, and $v - \delta v$ be the potential at the other end: then the current, i, at any instant, t, is determined from the fundamental equation,

$$L\,\delta x\frac{d\,i}{d\,t}+R\,\delta x\,i=\delta\,v \quad . \quad . \quad . \quad . \quad (33),$$

and the current and potential are connected by another relation,

$$\frac{d\,i}{d\,x}=C\frac{d\,v}{d\,t} \quad . \quad . \quad . \quad . \quad . \quad . \quad (34),$$

because the current flowing out of the element of length is less than the current flowing into the element by the condenser current taken up in the element.

Differentiating (34), and substituting in (33), we arrive easily at the equation,

$$L\,C\,\frac{d^2\,v}{a\,t^2}+R\,C\frac{d\,v}{d\,t}=\frac{d^2\,v}{d\,x^2} \quad . \quad . \quad . \quad . \quad (35).$$

This differential equation gives us the means of determining the potential, v, at any time and place in the cable.

Let v_0 be the electromotive force at the origin or the end of the cable at which the dynamo or electromotor is applied, and let V_0 be its maximum value—such that,

$$v_0=V_0\sin p\,t:$$

then, if the cable is infinite in length, the solution of the equation (35) can be obtained, and the potential, v, at any distance, x, from the origin, and any time, is easily shown to be given by

$$v=V_0\,e^{-P\,x}\sin\,(p\,t-Q\,x),$$

where the quantities P and Q are—

$$P=\pm\left\{\frac{p\,C}{2}\left(\sqrt{R^2+p^2\,L^2}-L\,p\right)\right\}^{\frac{1}{2}}.$$

and

$$Q=\pm\left\{\frac{p\,C}{2}\left(\sqrt{R^2+p^2\,L^2}+L\,p\right)\right\}^{\frac{1}{2}}.$$

For the Ferranti trunk mains the values of these quantities have been calculated in Section 14.

If the cable is not infinite in length, but has a finite length, l, then two cases may be considered—(i.) when the cable is short-circuited at the far end, and (ii.) when its two members are insulated or open-circuited at the far end.

Taking the first case of a concentric cable of length l, short-circuited at the far end, and attached to an alternator of negligible inductance and resistance at the other, Mr. Heaviside has shown how the potential at any distance, x, from the machine can be obtained, and also the current flowing through an ammeter placed at any point in the cable. If V_0 is the maximum value of the periodic electromotive force applied at the dynamo end, and v is the potential at any time, t, and any distance, x, from the dynamo end, then he gives the value of v as

$$v=V_0\,e^{-P\,x}\sin\,(p\,t-Q\,x)$$
$$+V_0\,\frac{e^{P\,x}\sin\,(p\,t+\theta_2+Q\,x)}{e^{P\,l}(e^{2\,P\,l}+e^{-2\,P\,l}-2\cos 2\,Q\,l)^{\frac{1}{2}}}$$
$$-V_0\,\frac{e^{-P\,x}\sin\,(p\,t+\theta_2-Q\,x)}{e^{P\,l}(e^{2\,P\,l}+e^{-2\,P\,l}-2\cos 2\,Q\,l)^{\frac{1}{2}}}$$

(see *Phil. Mag.*, Vol. XXII., September, 1886, p. 284.)

It can be shown from the above that the ratio of the maximum value, V, of the potential at any distance, x, from the origin, to the potential at the origin, V_0, is given by the relation,

$$\left(\frac{V}{V_0}\right)^2=\frac{e^{2\,P\,(l-x)}+e^{-2\,P\,(l-x)}-2\cos 2\,Q\,(l-x)}{e^{2\,P\,l}\quad+e\quad-2\cos 2\,Q\,l} \quad . \quad (36).$$

In the above equations P and Q stand for the functions of resistance, inductance, and capacity given above in Section 14, and e is the Naperian base.

The equation (36) enables the pressure at any point in the cable, as given by a voltmeter, to be predetermined from the pressure at the origin. The current flowing through a low-resistance ammeter placed at any point in the cable can also be deduced from the equation (36), and its maximum value, I, is shown by Mr. Heaviside to be given by the equation,

$$I^2=\frac{V_0^2\,C\,p}{\sqrt{R^2+p^2\,l^2}}\,\frac{e^{2\,P\,(l-x)}+e^{-2\,P\,(l-x)}+2\cos 2\,Q\,(l-x)}{e^{2\,P\,l}\quad+e^{-2\,P\,l}\quad-2\cos 2\,Q\,l} \quad . \quad . \quad (37).$$

This gives us the value of the dynamometer reading at any point in the cable. It shows us that if l is great enough the current flowing through an ammeter placed at the distant end of the cable would be zero.

Suppose, next, that the distant end of the cable is open-circuited, and that an electromotive force, of which the maximum value is V_0, acts at the home end. It is then possible to prove that under these circumstances the ratio of the maximum value, V, of the potential at any distance, x, from the origin to the maximum value of the potential at the origin, is given by the equation,

$$\left(\frac{V}{V_0}\right)^2=\frac{e^{2\,P\,(l-x)}+e^{-2\,P\,(l-x)}+2\cos 2\,Q\,(l-x)}{e^{2\,P\,l}\quad+e^{-2\,P\,l}\quad+2\cos 2\,Q\,l} \quad . \quad . \quad (38).$$

If $x=l$—that is, if we consider the potential at the far end, the numerator of the right-hand side becomes equal to 4, and hence if the denominator is numerically less than 4 for any given cable—it indicates that a progressive rise in pressure along such cable will take place from the machine end to the free or insulated end.

In a very able Paper in the *Philosophical Magazine* for January, 1887, p. 21, Mr. Heaviside has attacked the general problem of calculating the current flowing through a transformer at the far end of a concentric cable when an alternator or transformer giving a periodic electromotive force of maximum V_0 is placed at the other. The Paper is not an easy one to read, and was probably still harder to write. Some of the general results are, very briefly, as follows:— If L_0 and R_0 are the total inductance and resistance of the transmitter, whether alternator or transformer, and L_1 and R_1 the same quantities for the receiver, and L, R, and C the inductance, resistance, and capacity per unit of length of the cable, and V_0 the maximum value of the impressed electromotive force at the transmitter, and C_0 the maximum value of the current through the receiver, then

$$C_0=2\,V_0\frac{C\,p}{(R^2+p^2\,L^2)^{\frac{1}{2}}}\left[\begin{matrix}G_1G_0e^{2\,P\,l}+H_1\,H_0e^{-2\,P\,l}\\-2(G_1G_0H_1H_0)^{\frac{1}{2}}\cos 2(Q\,l+\theta)\end{matrix}\right]^{-\frac{1}{2}},$$

where G_1, G_0, H_1, H_0, and θ are complicated functions of the resistances and inductances of the receiver and transmitter, and which have the values,

$$G_0=1+(P^2+Q^2)\left(\frac{I_0}{I}\right)^2+(2\,P\,R+2\,Q\,p\,L)\,R_0+$$
$$(2\,P\,L\,p^2-2\,Q\,p\,R)\,L_0;$$
$$H_0=1+(P^2+Q^2)\left(\frac{I_0}{I}\right)^2+(2\,P\,R+2\,Q\,p\,L)\,R_0-$$
$$(2\,P\,L\,p^2-2\,Q\,p\,R)\,L_0;$$

and similarly for H_1 and G_1.

I_0, I, and I_1 are the impedances of the transmitter, cable, and receiver; and the quantities P and Q have the values given in Section 14.

The quantity θ is an angle which is determined from the expression,

$$\tan 2\,\theta=\frac{2\,(A\,b-a\,B)}{A^2+B^2-(a^2-b^2)},$$

where

$$A\,b-a\,B=(R_0+Q_1)\,(R\,Q-L\,p\,P)+(L_0+L_1)\,p\,(R\,P+L\,p\,Q)$$
$$-(R_0\,I_1^2+R_1\,I_0^2)\,C\,p\,P-(L_0\,I_1^2-L_1\,I_0^2)\,p^2\,C\,Q;$$
$$A^2+B^2=I^2+C^2\,p^2\,I_0^2\,I_1^2-2\,(R_0\,R_1-L_0\,L_1\,p^2)\,L\,C\,p^2$$
$$-2\,(R_1\,L_0+R_0\,L_1)\,p^2\,R\,C;$$
$$a^2+b^2=(P^2+Q^2)\,[(R_0+R_1)^2+p^2\,(L_0+L_1)^2].$$

Digitized by Google

The question whether the mean pressure at the receiver is greater than the mean pressure at the sending end, or less, will in general depend upon the sign of tan 2 θ.

The quantities G_0 and H_0 become equal to unity when the inductance and resistance of the sending instrument are zero or very small.

The practical deduction which may be made from the above investigation is, that when the alternator at the sending end has very small resistance and inductance, the pressure at the receiving end of the cable will be less than the pressure at the transmitting end, for almost any cases which occur in practice; but this is not always the case when the transmitting instrument has a sensible inductance. We may then have conditions under which there is a progressive rise of pressure from the sending to the receiving end.

The time at disposal has not permitted me to do more than sketch out the general results of such investigations as have been made on the propagation of periodic currents through conductors having sensible capacity and inductance. These investigations need to be brought into further comparison with the results of experience, in order that we may see how far they agree with observed facts, and how far they can be trusted as a guide in predicting the results of the application of known electromotive forces to conductor systems in which the capacity and inductance can be predetermined.

ON SOME POINTS CONNECTED WITH MAINS FOR ELECTRIC LIGHTING.*

BY WILLIAM HENRY PREECE, F.R.S., PAST-PRESIDENT.

1. I do not purpose in the following Paper to describe the mechanical details of the various systems of mains adopted in different places to transfer and distribute electrical energy. These most of us can see for ourselves by personal inspection in the various works now in progress in London, or can read about at our leisure in the numerous Papers that have been recently printed in the technical periodicals and in the *Journal* of our Institution. My object is to extol the "sweet simplicity" of the two-wire system, the practical security of concentric mains, and the unquestionable economy of the high-pressure principle. At the same time, I do not want to be considered an advocate of any one particular method. Engineering works must necessarily be considered a species of compromise. Conditions vary in different localities; difficulties arise in the most unexpected quarters; different ways of surmounting obstacles occur to different minds. What is good for one place need not necessarily be good for another. The independent engineer must keep his mind open; he must master his requirements; he must give every plan his consideration, and choose his best agents, despite the tyranny of the Patent Laws and the susceptibility of inventors. He must, however, be just, and see that merit is awarded and claims respected.

2. I do not intend to discuss overhead wires. I consider them, for high-pressure electric light circuits, an abomination, especially as it is easy to show that ultimate economy is in favour of the underground system. It is only the first capital expenditure that favours overground mains; safety, freedom from accident, ease of repair, and renewals are all the other way.

3. Broadly, the different underground systems in use may be classed into those which are *fixed* and those which are *movable*.

As a type of the first, I will instance the Ferranti concentric mains, that are buried solidly in the roadways, embedded in asphalte in wooden troughs, and which are inaccessible except by excavation; and as an example of the second, I will take the ordinary telegraphic method of burying cast-iron pipes, with occasional boxes, in and out of which cables new and old can be drawn at pleasure, and where the conductors are always accessible for the rapid removal of incipient faults should they develop themselves, and removable for enlargement should the system grow.

4. Again, we must divide the systems into *high* and *low pressure*, for under these two heads we have to consider not only the all-important questions of insulation and of finance, but those of security to person and to property. The line of demarcation between high and low pressure has been defined by the Board of Trade to be 300 volts; but in what follows whenever *high pressure* is mentioned about 2,000 volts is meant, and *low pressure* implies about 100 volts. There is one case only in this country where *extra high pressure* is used, and that is by Mr. Ferranti, whose adoption of 10,000 volts is regarded by so many with fear and horror. This voltage is, however, going to be exceeded this summer by the Exhibition authorities at Frankfort, who are going to draw 300 H.P. from the river Neckar, at Lauffen, 112 miles away, by a pressure of 27,000 volts.

* Paper read May 7, 1891, before the Institution of Electrical Engineer

5. The only limit to the use of extra high pressures, or to the voltage employed, is the efficiency, economy, and durability of insulating materials.

First and cheapest on the list is *air*, which, when dry, is the most perfect insulator known—its specific resistance being, in fact, immeasurable—which has the lowest specific inductivity, and therefore is taken as unity, but which cannot resist electric stress, and through which the sparking distance has a very poor figure of merit. The breakdown stress, or sparking distance, of dry air at ordinary atmospheric pressures may be taken to be for—

Direct currents	9,200	volts per centimetre;
Periodic alternating currents ...	6,000	,, ,,

between a disc and point.

Air is, moreover, hygroscopic, and very variable in its qualities; but there is no evidence that the variation of its saturation point affects its resistance or its inductivity, excepting that it tends to coat with moisture glass, porcelain, and other insulating supports, which are essential to keep up metallic conductors in position when it is used as an insulator, if their temperature falls below that of the air. The use of air was inaugurated by Mr. Crompton in Kensington, and his example has been followed by Latimer Clark, Muirhead, and Co. in St. James's, by Prof. Kennedy in Westminster, and by Prof. Robinson in St. Pancras. It has also been followed in Paris and in Germany.

6. *Gutta-percha* has been used almost exclusively for submarine cables, and for telegraphic underground wires in Europe; but owing to its scarcity and its high price it is rapidly being replaced by other materials, and, excepting in Paddington (Great Western Railway), where it was laid down by the Telegraph Construction Company, I do not know of its use for electric light purposes. It does not stand exposure to variations of temperature or of dryness. It is durable only in water, and even if it were plentiful it is doubtful if it were practical for electric light purposes.

7. *India Rubber* is more practical. Modern improvements in vulcanisation have brought it within the scope of the engineer and the range of finance. The addition of a small quantity of sulphur, subjected to high temperature, produces a new form of rubber, which makes not only an admirable insulator, but a waterproof, homogeneous, compact, and apparently durable compound. Our experience of this latter quality is, however, limited at present. The cables of this class manufactured by the Silvertown Company have justly acquired a high reputation, though several other firms are competing with them on equal merits. The weak point is in the jointing, which, unless properly done and thoroughly vulcanised, admits into the system numerous points of danger, which, sooner or later, will occasion engineers in charge many minutes of anxiety and worry. Compound rubber cables are used exclusively by the Metropolitan Electric Supply Company and by the House-to-House Electric Light Company, for their mains distributing high-pressure alternating currents. I am assured by both companies that up to the present time not one single defect has developed itself in their mains.

8. *Bitumen* is a mineral product of a pitchy character, imported into this country principally from Trinidad. The late Lord Cochrane tried hard to introduce it as an insulating medium, but it remained for the enterprising firm of Callender to make it a real commercial commodity. When purified, refined, and vulcanised it makes, combined with some vegetable fibre like jute, a tough elastic coating, proving it to be an active competitor of compound rubber. When used in its crude state it forms a solid mass, in which the more refined "bittite" can be embedded in an immovable and apparently indestructible and unassailable bed.

9. There are various waxes—*paraffin*, *ozokerit*, and other hydrocarbons—which have a high specific resistance and a low specific inductivity, that have been much used; but the most practical use of these materials appears to be their combination with brown paper, which has been introduced by Mr. Ferranti in his Deptford mains.

10. The refuse of crude *petroleum*—that is, petroleum after all the spirits, illuminating and lubricating oils, and waxes have been distilled or expressed—a thick, heavy black mass, liquifiable under high temperature, but almost uninflammable, and eminently adapted to resist high temperatures—makes an admirable insulating compound of very high specific resistance and comparatively low specific inductivity. It is the material used by the Fowler-Waring Company, and destined to enjoy a profitable career.

11. *Heavy resin oil* is an admirable insulator, filling, when hot, all the pores of vegetable matter, like jute and cotton, immersed in it, excluding all air and moisture from the conductor, having a very high resistance and a very short sparking distance, but, above all, being viscid and movable, so that any puncture is at once filled up by its own mobility, so that any fault occasioned by piercing is instantaneously self-cured. Oil has such excellent merits that it has been proposed by Johnson and Phillips to bury in it high-pressure

Digitized by Google

alternate-current transformers. Heavy oils discard water, owing to their density. They are inoxidisable, and, therefore, practically indestructible. Many failures in the use of oil as an insulator in the past have arisen from the use of oils of too low specific gravity.

12. There is one objection to most of these mineral hydrocarbons, viz., that they require to be encased in lead; but oil has this advantage—that it can be used in iron pipes in the method adopted by Brooks. Lead covering is expensive, and it adds seriously to the weight of the cable, so as to render more difficult its handling and drawing in and out. On the other hand, lead adds materially to the life of the cable. I have in my possession samples of lead-covered wire which were buried in 1844, and in which the conductor and insulating medium are now as perfect as when made. Lead, however, in some localities, especially in decaying vegetable matter, is itself attacked. When, however, properly protected, it ought to last for centuries. The lead used by the Romans to distribute water in Pompeii is still visible. Lead-covered cables are very largely used in America, Germany, and France, and their employment is rapidly extending in England.

13. All these materials, excepting air, are equally applicable for high and for low pressure: the thickness only has to be increased with the pressure; but we have yet to know what influence the rapid reversals of high-pressure alternating currents have upon the molecular structure of the material. The difference in the striking distance in air shows that the stresses in the two cases of direct and alternating currents are very different. Time alone will give us the experience we want as to the effect of these stresses on the texture of the dielectric used. It is this absence of experience that causes so much want of confidence in the use of extra high pressures.

14. The operation of Sir William Thomson's law, the relative economies of the two-wire, three-wire, and five-wire modes of distribution, the comparative cost of high and low-pressure, have been so frequently discussed, and are so thoroughly well-known, that they need no description here. Everyone will admit that as we increase the pressure driving the currents, we can diminish the size of the conductor; and although we have to increase the relative thickness of the insulating medium the actual quantity used remains practically the same. Hence, high-pressure means great economy in copper. The future of electric lighting is a financial question; its practicability and efficiency are beyond doubt. The lion share of the capital necessary for the extension of electric lighting over a district is required for the mains and conductors; an important item in working expenses is in their maintenance. Hence this is now the field for the exercise of economy. If we can reduce the cost of distribution and its up-keep by 50 per cent., we should be able to supply light by electrical energy more cheaply than by gas. It is a pity that some of that redundant mental energy which is endeavouring to raise the efficiency of dynamos and transformers from 94 per cent. to 95 per cent. could not be transferred to the question of mains, where real advancement and true economy on a considerable scale are much more required.

In Liverpool, Birmingham, and Bradford, low pressure is distributed by the original and simple two-wire parallel system. In Kensington and Westminster low pressure is distributed by the three-wire plan. The London Electric Supply Company, the Metropolitan Company, and the House-to-House Company distribute their high-pressure systems by two wires; but in Rome, where sub-stations are used, the distribution of low pressure is by three wires. In Germany distribution in some places is by five wires, and I have heard it mooted to distribute in Paris by six wires.

15. The points that determine the distribution of low pressure are fall of potential and number of feeding points and distributing stations. We need not consider the heating of conductors. If we take care of the potentials the waste will take care of itself.

One ton of copper of one square inch sectional area covers a length of 192·3 yards, and its resistance is ·0046 ohms. Hence, a length of 220 yards weighs 1·13 tons, and its resistance is ·00527 ohms. A pair of such mains will weigh 2·26 tons, and their resistance will be ·01054 ohms. 1,000 amperes means, therefore, a loss of 10½ per cent. (and one kilowatt is wasted in every 43·4 yards), 500 amperes means a loss of 5¼ per cent., and 237 amperes means a loss of 2½ per cent., in such a circuit when the full load is supposed to be concentrated at the end. If we take a fall of potential of 2½ per cent. in each main, which is the recognised maximum waste at full load allowed to comply well with Thomson's law, it means 474 amperes delivered at 100 volts, or 1,600 8 c.p. lamps served. In fact, we may say that two mains of one square inch copper will serve 1,600 8 c.p. lamps at 220 yards distance; and this appears to be the commercial limit of the two-wire low-pressure distribution. Of course, if we are content to admit a greater waste, this limit of distance can be extended, and the number of lamps to be served can be increased in the same ratio. The exact waste to be allowed is an economical question, governed a good deal by the conditions of the problem, financial as well as engineering. Now, if we add another 100 volts at the point of supply, we can deliver the same energy for the same number of lamps with the same loss, at 880 yards; and for every additional 100 volts delivered, we can extend the distance to which the supply can be driven under similar conditions, as the square of the unit distance, 220 yards, for to maintain the same energy the current is *diminished* in the same ratio. Thus, 2,050 volts will drive the energy required for 1,600 8 c.p. lamps 50 miles if we use mains of one square inch sectional area, and are satisfied to waste only 5 per cent. of the driving energy. Prof. John Hopkinson, F.R.S., showed how,* by the use of an intermediate third wire and two dynamos, we could use 200 volts with our present lamps, and therefore we could practically diminish for the same distance the weight of copper used by one-half, or we could make the same weight of copper serve double the distance. The third wire, however, diminishes the effective economy of the plan. Its practical commercial limit appears to be about half a mile; and its disadvantages to be, more dynamos to work, and considerable complication to adjust and regulate the equilibrium of lamps on the circuit.

The five-wire system, which is in use in Germany, enables us to use 400 volts at the point of delivery; and this, again, enables us to extend our area of supply, with the same weight of copper, to one mile, but with more dynamos, and with more regulation and balancing, and, therefore, with more complication.

There is no practical limit to the high-pressure system; 10,000 volts will drive energy from Deptford to London on two mains of one-quarter square inch section to serve 50,000 lamps; and 27,000 volts will drive 300 H.P. 112 miles, from Lauffen to Frankfort, on a conductor of ·06 square inch sectional area, *i.e*, a No. 2 copper wire.

16. But we have to take into consideration the difficulties of the distribution.

On the two-wire system this means one central station for each effective area having a mean radius of 220 yards. On the three-wire system this area can be extended to a mean radius of one-half mile; the five-wire system extends the mean radius to one mile; but with the high-pressure system the area is practically unlimited in extent. When the mains and feeders are at high pressure, and the distribution at low pressure by two wires, we must contemplate *sub-stations* serving areas having a radius not exceeding 220 yards, if the lamps be uniformly scattered over the area and our waste energy is kept low.

A transformer sub-station is a very simple and cheap structure. It may be excavated underground, or be in a cellar, or in a back-yard. The instruments are stationary. They require no oiling, nor adjusting, nor handling, nor even tending. They can be buried in oil and suffer no deterioration. They are simple in construction, and should need no repair. Switches to throw them in and out of circuit may be automatic or manual, and can be operated from outside the transformer room, as is done in Rome.

17. The sub-station high-pressure system has been thoroughly worked out in Rome. Every nest of about 2,000 lamps is served from a sub-station containing a bank of 12 transformers, each of 7½ kilowatt capacity. Means are provided to cut transformers in and out as the load comes on and off. The great waste of the idle transformer is thus prevented, and by banking them in this way only half the total number of transformers is required. Moreover, it enables the most efficient transformers to be used, and always at full load. It is well known that the efficiency of a transformer increases with its size. Mr. Ferranti has already reached 100 kilowatts without reaching a limit to this law. Distribution by two wires on this limited scale is of the most economical and effective kind, and there is no complication of adjustment of current or regulation of pressure. Each sub-station serves, as a rule, in Rome, one block of buildings, so that generally the high-pressure mains alone are underground. The pressure is 2,400 volts. The distribution in Rome is by three wires—not, however, for any economical reason, but simply to allow arcs and glow-lamps to work on the same network without interference and without waste. The counter electromotive force of the arc prevents arc lamps from being registered accurately on any of the existing meters, but the three-wire plan enables the arcs to be served separately from the glow-lamps. Arc lighting is in great request in Italy, especially for shop-lighting.

The chief difficulty the engineer has to encounter is to know his users and the extent and character of the supply. This is now generally guesswork. It is difficult to estimate the actual load factor. We have to take the gas supply as our criterion, and to judge of the probability of obtaining customers from the character of the residents and occupants of the district.

18. It is impossible to serve economically a wide and scattered district with a mean radius of over one mile by any other means

* John Hopkinson, Patent No. 3576, July, 1882.

Digitized by Google

than by high pressure, for we cannot multiply central stations without seriously increasing capital outlay and working expenses; unless, indeed, the density of supply be very great, as it is in some quarters in London and in some of our large provincial cities.

19. Let us assume that we have a wide and scattered district to serve, and that we are going to supply at high pressure, and to distribute by two wires from sub-stations: the problem we have to solve is, what shall be the character of the high-pressure mains and feeders connecting the central station, or stations, and the sub-stations?—shall they be separate conductors or concentric cables? We will also assume that the weight of copper and quality of insulation is the same in each case, and that their prime cost is

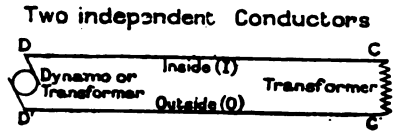

Fig. 1.

Fig. 2.

not materially different, although, as a matter of fact, for the same distance the concentric main, if made of the same materials, costs less than the two separate conductors.

It is, therefore, a question of *adaptability*, *security*, and *freedom from disturbance*. To study these points we want to know how the potentials are distributed on such conductors.

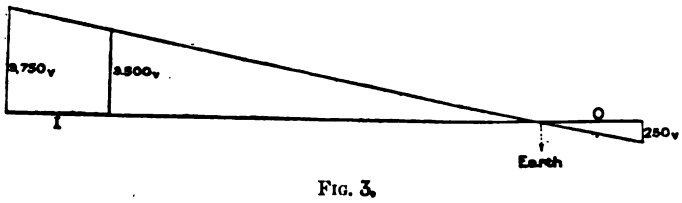

Fig. 3.

If we consider two independent conductors (Fig. 1), lying side by side in the same pipe, or conduit, connecting the two poles of the dynamo, D and D', with the transformer, C C', and we call the *go* wire the *inside* (I) and the *return* wire the *outside* (O)—then, if we represent the effective resistances at any moment of the transformer by the straight D D' line (Fig. 2), D C can represent the resistance of the inside conductor, C C' that of the transformer,

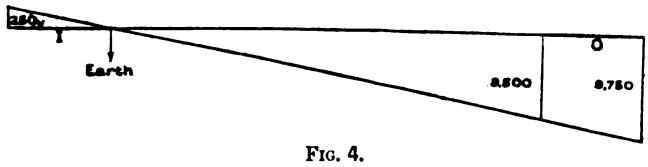

Fig. 4.

and C D' that of the outside conductor. If the ordinate D *d* represents the positive pressure when at its maximum and the transformer on full load, then, if the pole D' be connected with earth, the slope of the line will indicate the simultaneous pressure at any point of the circuit, and the difference between the ordinates will give the fall of potential between any two points; that is, there is

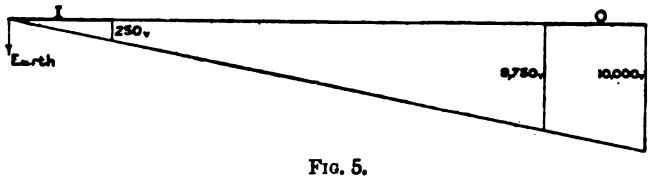

Fig. 5.

a fall of 250 volts in each conductor, and if the circuit be carrying 50 amperes there will be a waste of 12,500 watts in each conductor. If the line O were in its proper position and direction alongside I, as in Fig. 1, it would be seen that the difference of potentials between any contiguous points is everywhere 10,000 volts.

Now, if the earth be transferred from D' to the negative pole of the transformer, C', the pressure at the similar phase will rearrange itself as shown in Fig. 3; and Figs. 4 and 5 give the same information when the earth is consecutively fixed at the other pole of the transformer and dynamo. Fig. 6 shows the distribution when the centre of the transformer is to earth, or when there is no earth.

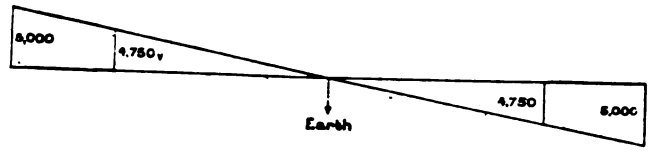

Fig. 6.

It will be seen in each case that the fall of pressure remains the same; the difference between the potentials between the conductors remain the same: it is the sign and the difference of potential between each point and the earth that has altered. Fig. 7 shows the distribution when the transformer by some accident is disconnected, and Fig. 8 when it is short-circuited.

I have not considered the variations of potential due to the rise and fall of the currents, and I have ignored the dynamo—the

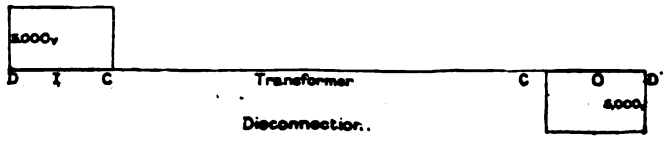

Fig. 7.

potentials being those at its terminals. Frequency, inductance, impedance, besides capacity and resistance, enter to complicate matters and to deprive the graphical method of that simplicity which is shown by the figures. But Dr. Fleming has exhaustively dealt with this subject analytically and in a masterly manner.

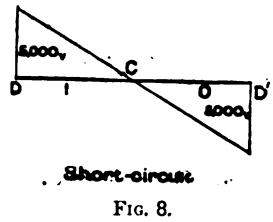

Fig. 8.

20. Now, Mr. Ferranti's mains are concentric, and their capacity must be taken into consideration. Fig. 9 shows these capacities, that between the two conductors being ·35 microfarad per mile, and that between the outer tube and earth being 3 microfarads

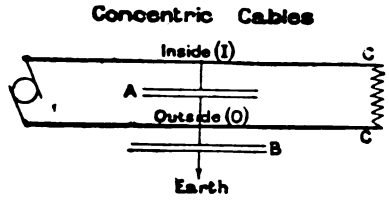

Fig. 9.

per mile. Figs 10 and 11 show the distribution of pressures when the earth is on and off the pole of the dynamo. The remarkable fact comes out that whether the pole be to earth or not the difference of potential between the outer conductor and

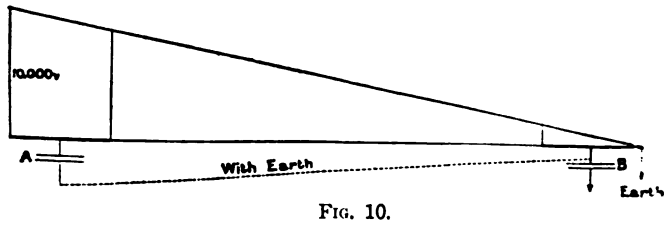

Fig. 10.

earth of a concentric cable is practically the same in each case. It does not exceed 250 volts in either case, and, therefore, the cable could be handled with impunity while the current was flowing and all connections were right, but if a fault arose—disconnection or short-circuit—then the result might be

Digitized by Google

serious. A long length of perfectly insulated cable with considerable capacity is practically in the same position as though it were connected to earth. The surging in and out of the cable of the electrical quantity dependent on the capacity and the impressed electromotive force, produces the same effect at the terminals as the periodic flow of current through the cable when the distant end is to earth. The effect of capacity is to lower the potential, and when its magnitude is sufficient it reduces the potential of the conductor to that of the earth, for it does not allow time enough for the charge to accumulate. Hence, a concentric main, whether its outer conductor is connected to earth or not, has its potential reduced practically to that of the earth. The use of the earth is imperative to dissipate the static charge and to secure safety. A permanent and efficient earth makes the cable safe to person, and dangerous to apparatus only, which can be fully protected by fuses. Unless, however, it is most effectively applied, it may become a source of danger to person also, and of disturbance to telephones, for the existence of a variable fault might produce a shifting of potentials which would destroy the security.

It is very easy by the aid of such diagrams to study the distribution at any phase of the potential, or at any instant of flow. The capacity acts as a kind of break or damper on the currents, and its tendency is to vary the rate of rise of potential, and to flatten the curve of rise and fall of the currents. With direct and intermittent currents it acts as a fly-wheel, but with alternate currents it acts more as a spring, or as an air cushion in a hose-pipe. Its effect with ordinary frequencies is not material; but the rapid alternations of stress and displacement in the dielectric must have a tendency to heat that material. It will be readily seen how the earth dissipates the charge at once, but it also shows that when a disconnection takes place this discharge may be very unpleasant.

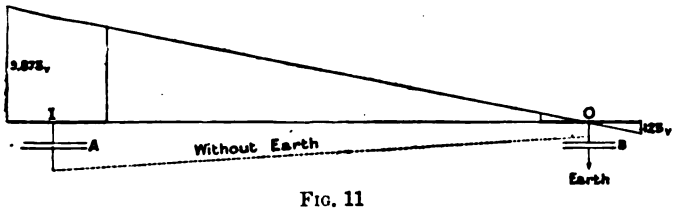

FIG. 11

(To be continued.)

SOME RESEARCHES IN ELECTRO-MAGNETIC INDUCTION.

The following is a full report of the interesting discussion which followed the reading of Mr. E. B. Vignoles' Paper on "Some Researches in Electro-Magnetic Induction," presented at the Old Students Association on Wednesday, May 13th :—

DISCUSSION.

Dr. W. E. SUMPNER said that he quite sympathised with the wish of Mr. Vignoles and his co-worker, Mr. Evershed, to put the subject in a very clear manner. An immense amount of work had been done with regard to magnetism, but there had never been any Paper which had put the subject so briefly and clearly as Mr. Vignoles had been able to do. It compared very favourably with the admirable series of articles by Mr. Evershed in *The Electrician* on transformer questions. There were one or two points, however, in which he thought Mr. Vignoles might have stated matters a little more happily. He thought he had rather confused the meaning of "line of force" with "line of induction," and had not really grasped the full value of the meaning of lines of force. Mr. Vignoles advised them to confine the idea of lines of force or lines of induction to symbols of direction and not of quantity. As had very often been explained, they could very easily be made to represent both. The direction of the line represented the direction of the force, and the density of the lines represented the strength of the force. It was also very unfortunate, especially as Mr. Vignoles pointed out very clearly the need of distinguishing between induction and induction density, that he should have represented the value of **H** in dynes, because he there assumed that magnetic force was mechanical force. Dyne was, of course, the unit of force, but it was not true that **H** was represented in dynes. **H** is not a mechanical force, any more than electromotive force is mechanical force. Each represents a mechanical force in conjunction with some unit, one of magnetism the other of electricity, but neither is a mechanical force by itself. It did not follow because the unit of magnetic force was a mechanical force on a unit of magnetism that a unit of magnetic force was a dyne. With reference to Mr. Vignoles' experiments, there was one point that he did not understand very fully. He said that he proved by experiment that the throw of the galvanometer was inversely in proportion to the resistance of the galvanometer circuit; and he then went on to show and to give a curve in which he corrects according to the resistance of the galvanometer circuit, and finds that he has to add to the throw various percentages, according to the resistance of the circuit. It seemed to him that those two statements could not be correct, and that one contradicted the other. He would like to hear from Mr. Vignoles more fully what he meant with respect to the matter. He had no doubt that Mr. Vignoles had got correct results from actual measurements. The method itself was novel in one respect—viz., that he got a throw corresponding with the complete step from one corner of the curve to the particular point which he wanted to determine. Of course, Ewing got the curves by taking successive steps and adding them together, but there was a danger of the state of the iron varying during the experiment—that is to say, while the experimenter was not noticing it the curve of induction might travel up a little bit. There was the same sort of objection, theoretically, at all events, to this method—that is, that the experimenter must keep his current in the first circuit quite constant, or he would move the corner of his curve. He thought, theoretically, that the objection to Ewing's method was the same as the objection to Mr. Vignoles' method, but that both could give perfectly good results. He did not think, however, that the method of Mr. Vignoles was necessarily a great improvement on that of Prof. Ewing. He might mention that, two or three years ago, in the laboratories at the Central Institution, a method bearing certain resemblances to this was used. The object of it was not to get the whole step from the corner of the curve to the point that was under investigation, but to get the slope of the curve at any point. In order to do that it was only necessary to determine the self induction of one of the coils for various currents flowing through the other. That gives a curve which is related to the curve of induction which Mr. Vignoles has been investigating. There was one point which ought to be clearly borne in mind, that was that in a transformer the current in the two coils is very much in excess of the magnetising current. If one wanted to determine the induction for a cycle of 10 amperes magnetising current, there must, to correspond with the transformer, be currents of 100 amperes or more in the coils. He would have liked to have heard a great deal more about those curious results which Mr. Vignoles had noticed as to the shifting of the curve along the axis of magnetic force. It was a very strange result, one which there was no theory at all to account for, and one which showed that it was impossible to apply the theoretical results, or to assume that results obtained by ordinary theory were applicable necessarily to alternating currents.

Prof. THOMPSON said that he very much appreciated the great patience, and skill, and trouble that had been taken in this research, and he was quite sure that it would bring its author great credit They ought to congratulate the author and themselves on having been the recipients of a Paper of such quality. That, perhaps, was all the more reason why he should say plainly that there were one or two little things in the Paper which he did not like at all. In the first place, he wanted to say as plainly as he could that he objected altogether to his use of the word induction for the total number of magnetic lines that passed through the iron. The word induction was used unhappily in something like half-a-dozen different senses already, and now Mr. Vignoles was going to add another. That fact was a very good reason for not using it at all. The word induction came in originally when people had the notion of action at a distance. Why should they retain the mistaken notion that electricity or magnetism or anything else was *induced* by action at a distance instead of being *produced*? The word induction, if it was retained for action apparently at a distance, ought to be kept for the production or generation of magnetism in some thing which is not in contact with, but which is at a distance from, the thing which is acting upon it. He was very sorry indeed that the word induction had ever been used for the production of magnetism through the iron itself in any one of the ways represented. He tried himself, as far as possible, to avoid its use. It was not a Paper at all on electro-magnetic induction. By the term electro-magnetic induction he always supposed was meant an induction such as Faraday discovered in the way of moving across the magnetic field. Now they were going to have it used in an entirely new sense. The other criticism was one that had already been touched upon by Dr. Sumpner—that is, the use of the conception of lines of force. He did not see why they should not use this term in a quantitative sense, as Faraday did. He begged to remark that the iron did not know the difference between the lines of induction and the lines of force. If there were **B** lines going through the square centimetre some of those **B** lines would be there if the iron was not there, and then you would call them **H**, but the iron does not remember which part is **H** and which is not **H**. Therefore, looking at the thing from the point of view of the iron, he was quite entitled simply to call them magnetic lines. Now, to come to the substance of the Paper, he was inclined to think that some criticisms passed upon Dr. Hopkinson's method were based upon an illusion. If the sketch on the board were anything more than a qualitative representation of Dr. Hopkinson's results, then the criticisms would be justified; but it did not qualitatively represent Dr. Hopkinson's apparatus at all. He did not think the author had ever seen Dr. Hopkinson's apparatus. Referring to the illustration, Prof. Thompson said that any notion that there would be serious hysteresis in the chunk of iron was simply absurd. Again, he thought far too much had been made about the question of the resistance or reluctance of the gaps. They knew how much to allow for the reluctance of the well-surfaced gap since the experiments of Ewing, and even if there were a leakage of magnetic lines at the ends, that would not affect the middle where they were making the measurement by the tenth of 1 per cent. in the actual apparatus. He did not know whether Dr. Hopkinson made any allowance for the effect of the junction in the middle, but if he did not it would be perfectly easy to do so. Ewing did not go to the zero point every time, but simply came back and supposed zero in the middle. Here he thought the author deserved great credit for having pointed out the desirability of going to the fixed point, namely, one end or the other of the cycle. He quite appreciated the importance of

Digitized by Google

that, but he did not think they ought to overlook the fact that Ewing, though he went step by step, did take pains to check his results. He came back to approximate zero in the middle, and returned by a long jump to see if the long jump did not come to the same thing as the separate small jumps which were made in the course of the observations. In winding the rings in the way that had been pointed out, there was one point of importance that had not been noticed, that the coils ought to be wound so as to return along their own path to the place where they began. Suppose they were winding a coil on to a ring, the authors said that they wound it all round the ring. That was quite right if they wanted to take the average, but it was quite wrong if they put air-gaps into the ring. It was not enough simply to wind it round, and finish off at the place where they started. They should go on winding backwards right back again, so as to finish off where they began, to have the two ends of the coil brought out together. The reason of that was to avoid a spurious effect in the galvanometer circuit which might be due to static charge of different parts of the wire. He had himself found in certain experiments that he made that this was decidedly a thing which ought to be allowed for. With respect to the very curious irregular cycle which the authors obtained from certain specimens of iron, he might say that in certain specimens that they had examined at Finsbury they found the same sort of thing. There was one piece of iron with respect to which every group of students who got it found the same thing, that the cycle was shifted on one side. They could only account for it by supposing that that particular specimen itself remembered which way it was magnetised. He could not believe that to be consistent with the statement of the authors, that the iron did not remember which way it was magnetised, for he thought that that proved that it did. There was a reference in the Paper to Ewing's experiments on tapping, which he thought was a little beside the mark. If he remembered rightly, Ewing's results, in which he got such great alterations in the residual or permanent magnetism, related only to rods, and not to rings, and he could quite understand that there was a difference between the two. There was a very important observation, though not altogether new, which he supposed the author would admit was important, which was that a very small application of the electric current, either along the direction or at right angles to it, would take out all residual induction. Perhaps he might be allowed to refer to some old experiments of Wiedemann on that matter, and also to a very recent Paper published in *The Electrician* some few weeks ago by Dr. Finzi, where he showed that if he passed an alternating current through a piece of iron while magnetising it its effect was such that there was no residual magnetism, no hysteresis. The ascending and descending curves lay exactly on top of one another, and both of them conformed to the much abused formula of Frölich. There was another important matter, where the authors recommended large resistances in the secondary circuit. He entirely agreed that all experience showed that that was quite necessary. He would like to relate an incident with respect to that matter. He lately had a letter from the manager of an important physical laboratory asking him to explain to him a difficulty which had occurred to him, which was this: he was making experiments on rings and getting deflections, using a ballistic galvanometer, and he could not for the life of him understand how it was that it made no difference to them if he shunted the ballistic galvanometer down to the hundredth or thousandth part of the circuit. The deflection was the same when the block was in the lowest shunt, or when the block was in no shunt at all. He need not say what the reason was; it was precisely what one found with every well-built shunt dynamo in which there was very little resistance in the armature. Might he ask what the authors meant by saying that "Curve 7 exhibited in a comprehensive manner the results of the tests taking average permeability"?

Mr. VIGNOLES: As a matter of fact, we take the average curve to be the one which lies midway horizontally, that is to say, we take the average magnetising force for each value of B. They had assumed that that was the sort of average condition in which the iron was.

Prof. AYRTON said he quite agreed with what had been said about the value of the Paper and the amount of time and patience which must have been required to carry out these experiments. He must also agree with a good deal that had been said of a critical nature. He did not quite follow the first part of the Paper, where Mr. Vignoles proposed to give up lines of force from their quantitative sides and introduce the Thom—that was to say, he did not know what a Thom was. Mr. Vignoles said that the Thom did not suggest anything in particular, and he quite agreed with that; but possibly it might be as well to state what it was that he intended it to suggest. Mr. Vignoles said, "The Paris Congress has adopted a unit of induction density called the gauss." He presumed that that was true, but he was also sorry to say that at that moment he had quite forgotten exactly what a gauss was. He saw a certain advantage in this method of using, in the experiments on iron, what might be called the two magnetising coils method, the advantage arising when they wanted to pass from the negative magnetisation to the positive magnetisation. No doubt it would be possible with a single magnetising circuit to effect the same result, and reduce the current to the smaller value and reverse it at the same time; but it was very likely more easy to do it in the way that the authors had done, having ten amperes, or whatever it was, in circuit P_1, then to arrange such a resistance in the rheostat of P_2, that on starting the current P_2 the magnetising force was suddenly changed from its maximum negative value to the required positive value. Whenever that circuit was closed it would carry the magnetisation through its negative range, through O, to the required positive value; it might not be impossible, but it would be difficult to do that with a single circuit. He would suggest, too, that the secondary coil should have been wound close to the iron under the primary coils, as that would have got over the difficulty in the induction of the air space. With reference to Table 3A and the curves, he did not quite see why there should be a greater total induction—there might be a greater permeability.

Mr. VIGNOLES: No, is the induction density.

Prof. AYRTON: That showed the confusion that was caused by using words in a new sense—that was the same thing as permeability; it was not the total induction. He would not enter into what Mr. Vignoles called the "Mordey effect," except to suggest that he did not know whether it was wise to give these effects various names, because in a short time they would have all sorts of effects, A's effect, B's effect, &c., and it would be difficult to remember one effect from another. These effects merely stated what nature was, and why they were to be called by all sorts of different names he could not understand. If the particular effect in question was to be called any name, he would suggest that it should be called "the Central Institution effect," for the simple reason that in 1888 there were experiments made by students there, the results of which it seemed impossible to explain except by the diminished loss in the iron of a transformer as the load increased up to a certain point. For, in spite of the increased loss of power due to the heating of the primary and secondary coils as the load increased, the efficiency increased rapidly up to a very high value for a large load, and which seemed to indicate that the loss in the iron at this point was less than Prof. Ewing's results would lead one to expect. Prof. Ewing quite agreed with those experiments made at the Central Institution being possibly correct, since the iron in a transformer, and the iron he experimented with, were under very different conditions, and he thought that the experiments which Mr. Vignoles had made in his Paper threw absolutely no light on the matter. It was possible that in order to obtain exactly the conditions, they must have two large magnetising currents in opposite directions, slightly different in phase. He did not say that because there were those peculiar conditions that that was the explanation of the effect, but he did say that if any experiments were made, short of having two large magnetising currents in opposite directions differing in phase, and those experiments showed that there was no going down of waste on account of hysteresis as the load increased, the matter was open to doubt. It seemed to him that only with the transformer itself, or what was equivalent to the transformer, could they hope to get conclusive results. What they wanted was two large currents, roughly speaking, in opposite directions, but differing in phase. There was one other point in connection with this subject, and that was the experiments he had described at the Physical Society. He was speaking of the more recent experiments. The original experiments were made by means of the calorimetric method, but the more recent were carried out with Mr. Blakesley's dynamometer method. The proofs of the accuracy of Mr. Blakesley's method of measuring the power given to the primary of a transformer, as far as they had been given up to that time, assumed that there was no magnetic leakage. Prof. Perry had told him, in conversation, that he had proved that the split dynamometer method, even with leakage in the transformer, gave quite correct results. If that was the case, he was not aware of any error in the experiments that were described at the meeting of the Physical Society this spring. That would be an additional proof that there was a diminution of waste in the iron of a transformer, with increasing load up to a certain point. He had again to congratulate Mr. Vignoles and Mr. Evershed for the valuable contribution they had made to our knowledge of magnetism.

Mr. RUDDOCK thought that the gauss was more necessary than the thom. With reference to the curve shifting along the axis, as described on page 4, he did not see how the suggestion could hold in this case, because the iron was not magnetised at all between the two experiments, but simply had its scale taken off.

The PRESIDENT (Mr. W. B. Esson) said Prof. Ayrton had suggested that there should be definitions of the thom and the gauss, but he would suggest that the two terms ought to be struck out altogether, for he did not see the use of them. There was nothing indefinite about lines of force that he could see, and everyone knew very well what a line of force was, and that lines of force represented not only direction, but also quantity. There was one very practical point in the Paper having reference to the effect of removing the scale from soft iron plates. The results obtained by Mr. Vignoles and Mr. Evershed were the same that had been obtained by himself in a somewhat different way. He did not make a research, but he made up two dynamo armatures, in one of which the plates came direct from the annealing furnace, while in the other they were pickled, there being no difference in the result, which he supposed corresponded with what Mr. Vignoles and Mr. Evershed found. He would like to ask whether Mr. Vignoles had made any experiments with an alloy of iron and aluminium. He had two dynamo fields made, one having magnets of ordinary cast iron, and the other being a mixture of iron and aluminium, known as mitis metal, but when they came to test them, they found the alloy only gave about 5 per cent. more than the other; that was to say, with the same magnetising force, the induction at any part of the curve was only 5 per cent. more, so that he was afraid the advantage he got scarcely paid for the amount of aluminium put in. He would like to know whether Mr. Vignoles had made any experiments of that kind, for he must confess that he was rather disappointed with his results. Calculating the resistance of the magnetic circuit in both cases, and taking the permeability of the alloy as given by Prof. Thompson, they certainly ought to have been much better than he found them.

Mr. EVERSHED said, with regard to the objections that had been expressed to the use of the thom, it was not intended that every one should adopt it, but they could use it or not as they pleased. When he and Mr. Vignoles began the experiments, they thought they would like to understand each other, and that it was very desirable to use words of one syllable rather than more lengthened phrases, so they had thought it desirable to use the word "thom" in the sense in which it had been used. He had still another objection to the use of the term "line"; it might be feebleness of intellect, but when they came to talk about the earth's field being ·18 of a line he could not think of that, though when it was called ·18 of a thom, he could understand it. The method

Digitized by Google

they had used for obtaining the scale of their ballistic galvanometer did not involve a logarithmic decrement—that was to say, all that they had done was to leave out of account altogether the logarithmic decrement. They found that it was easier to assume that the galvanometer had no law at all. They then got what was absolutely a straight line, every one point on the curve being the mean of some half-dozen observations. The method of correcting to infinity was only a convenient one—they might correct to any resistance they liked, but infinity seemed to be more convenient. With regard to Prof. Thompson's observations on the question of damping, the coil which was used certainly had a current maintained in it. He pressed the key and kept the key down, and, as they knew, if there was no damping whatever the maximum throw of the galvanometer was twice what the steady deflection would be. They always got the same deflection, so that they could always ascertain what percentage that deflection was reduced by if the galvanometer circuit was closed through any particular resistance. They did not have to think about the damping produced by that circuit, because it consisted of one wire tacked down on the table on which the galvanometer stood. A great deal had been said about Prof. Ewing's method. They had not criticised it in any carping spirit. They were engaged on different work, and wanted to find out what iron did in a transformer, so they wanted to make it jump from one definite point to another at the other end of the curve without waiting between. Unless Prof. Ewing had a magnetometer which would enable him to take the reading instantly, he did not see how he could do it so quickly as they had done; as a matter of fact, they had taken curves with the ballistic galvanometer by taking small deflections one after another, and then found the sum of all the deflections was 10 per cent. under the deflection which they would get if it jumped from the bottom up to the top suddenly. One of those curious results, namely, the shifting of the curve in a ring of iron showed that apparently there was an induction—he did not know whether they called it an induction or production—but there was something which he called induction in that ring, and something which they could not get out except by reversing the magnetising forces. If they subjected one of those rings which had its cycle shifted to one side of the axis of induction to half-a-dozen strong reverse cycles of magnetising force, the chances are that the curve they took afterwards would be symmetrically disposed about the axis. There was no doubt that if they took the theory of the damping, in which the logarithmic decrement came in, and worked it out, in a case where the needle of the galvanometer only moved through a very small angle they could easily see that the total induction coming from the needle never got outside the coils. When the needle moved through a large angle the laws of its motion became so complicated that they were obliged to use logarithmic decrement, but when it only moved six or seven degrees there was no necessity to do so. The theory indicated that it was a rectangular hyperbola. Of course, they might really assume that it was a rectangular hyperbola, but they preferred to make the experiments, and to be perfectly sure that they were right.

Mr. VIGNOLES said he hoped the results described might be of use to somebody. Dr. Sumpner and several other gentlemen had made remarks about thoms and gausses. It was quite easy to understand that they preferred to talk about a thom, instead of talking about the "line of force." Thom was short, and did not commit them to anything. A gauss, of course, was one thom per square centimetre; they were only convenient names. As to what Prof. Thompson had said about induction, of course he had not gone into the history of electricity to the same extent as Prof. Thompson, and he was not aware that Faraday was the man who first used "induction" for "magnetisation," but they had found the word induction being used in the sense of magnetisation, and they found it a very good one, and therefore they used the word induction in the Paper. In their own case, the only thing they wanted to do in talking of induction and induction density, was to distinguish between the total amount of induction and induction density. He had not used the words in a new sense. Some people talked of induction when they meant induction density; but he and Mr. Evershed had confined it to the total induction. Dr. Sumpner had made some remark about the shifting of the curve along its axis.

Dr. SUMPNER said it was not a critical remark at all, but he alluded to its being so very strange that he would like to hear more about it.

Mr. VIGNOLES said he could not tell any more than he knew, which was this, that when they plotted the curve, they found that, instead of being as it should be, there was displacement along the H axis. He did not know why it was. It might be due to previous magnetisation of the iron bars, but they had never been able to produce it when they tried. Prof. Thompson had made some remarks about Dr. Hopkinson's method. When they had a joint there it must affect the distribution of the magnetising force, and, therefore, that distribution could not be calculated unless they allowed for the magnetising force which was used in those joints. As to the broomstick being 40 times its length, the two things were perfectly different, but that did not matter.

Prof. THOMPSON: Then why does it matter in Dr. Hopkinson's case?

Mr. EVERSHED said he thought that the real reason was that in the case of the broomstick they could calculate how much error was introduced. In Dr. Hopkinson's method it was the same thing really, only they could not calculate it.

Prof. THOMPSON: Yes, that is quite right, only there is so little to calculate for, because of the enormous section of the iron.

Mr. VIGNOLES: With regard to the displacement which had been referred to, that might have been caused between two observations by putting both coils in the same direction, as Mr. Evershed had suggested. If they happened to put on the wrong coil first they might get an error in that way. It only remained for him to thank them for the very kind way in which they had received the Paper.

LEGAL INTELLIGENCE.

Mangan v. Metropolitan Electric Supply Company.

This action, which was heard on Wednesday, before Lords Justices Lindley, Bowen, and Fry, is brought in the Chancery Division, claiming an injunction to restrain the continuance of an alleged nuisance arising from noise produced by the working of electric machinery in Manchester-street, Manchester-square. The plaintiff also claims damages. The plaintiff applied for and obtained an interlocutory injunction to a limited extent, but a second application for an injunction was refused. The plaintiff afterwards applied, by summons in Chambers, for an order that the action should be transferred to the Queen's Bench Division, and be tried with a special jury. On this summons, Mr. Justice North made an order for transfer, and he refused a subsequent motion by the defendants to rescind the order. The defendants appealed.

Mr. Napier Higgins, Q.C., and Mr. J. G. Butcher were for the appellants.

The Court suggested that the best course would be to refer the action to an official referee for trial.

The defendants' counsel were willing to consent to this course, but Mr. Cozens-Hardy, Q.C., who (with Mr. Percy Gye) appeared for the plaintiff, declined to consent.

The Court dismissed the appeal, but reserved the question of the costs until after the trial.

LORD JUSTICE LINDLEY said that in substance the Court was asked to order Mr. Justice North to try the action himself after he had come to the conclusion that it would be better tried with a jury. The action was an ordinary one for a nuisance, brought in the Chancery Division. By means of the two motions for an injunction the learned judge had acquired a knowledge of the case. The plaintiff originally selected the Chancery Division, but he afterwards thought a jury would be a better tribunal for the trial than a judge alone. Mr. Justice North transferred the action to the Queen's Bench Division in order that it might be tried with a jury. This Court was asked to set aside the order on the ground that the learned judge, in exercising his discretion, had attached undue weight to the difficulty of assessing the damages. The appeal would be dismissed, but the costs would be reserved until after the trial.

LORD JUSTICE BOWEN and LORD JUSTICE FRY concurred.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May* 16, 1891.

Gearless Motors.—Just now the most active part of electrical industry seems to be the street railway business. The two gearless motors that have already appeared have met with such success in experimental use that large numbers of each kind have been ordered, and a month or two will probably see a considerable number in use. The great question that remains to be settled is the durability of these machines. They are likely to have an electrical efficiency somewhat lower than that found in the ordinary geared motors, and the question naturally arises what would be the result of this when the machine is put to a very severe test in climbing heavy grades under adverse conditions—will the motor stand it? On the whole there is every reason to think, from the experiments tried so far, that it will stand it, although a few months of experience may teach some special precautions that will have to be observed to secure durability. Another point in question seems to be the effect of severe vibration on the windings of the armature. Some electricians seem to fear that this would produce frequent short circuits. The Short Electric Railway Company in bringing out its gearless machine endeavoured to dodge any possible trouble from this source by very careful cushioning. The Westinghouse Company, on the contrary, boldly put the armature directly and rigidly upon the axle, depending on solidity of construction and firm winding to shield the coils from harm. Both motors have stood experimentally very severe tests, and their respective performances will shortly furnish an interesting subject for study.

The Westinghouse Company.—The Westinghouse Electric Company has apparently emerged successfully from its financial difficulties, and is taking a very active part in the electrical operations of the present season. In spite of all sorts of rumours started by its rivals, Mr. Westinghouse succeeded in reorganising and putting the Company on a firm basis. The details of the arrangements that have been made will become public in a few days, but it is sufficient to say that some of the most prominent capitalists in New York City are now among

Digitized by Google

the backers of the Company. In the letter last winter, when the difficulties were first announced, I expressed the opinion that such would be the outcome, and that confidence has been amply justified by the events of the past few weeks.

CORRESPONDENCE.

WESTMINSTER ELECTRIC SUPPLY CORPORATION (LIMITED).

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have just seen in your paper of last week Sir Wm. Thomson's Report on the electric lighting of Glasgow. I must ask you to allow me to correct a mistake which Sir William has there made. The system of feeders and network which I have laid down in connection with the work of the Westminster Corporation is neither identical with, nor even similar to, that described in Edison's English patent. If Sir Wm. Thomson had inquired into the details of the method I have adopted before he wrote his report, I feel sure that he would not have made the statement which I ask you to allow me to contradict.—Yours, &c., ALEX. B. W. KENNEDY.

19, Little Queen-street, S.W., May 25, 1891.

ELECTRIC LIGHTING AT GLASGOW.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I wish to call your attention to the fact that there is an arithmetical blunder in Mr. Crompton's calculations on the above subject. In his estimated cost of production of electricity he gives the cost of 400,000 units generated at Partick as £6,809. 1s. This is made up of—Cost, exclusive of engine-room expenses, £4,702. 13s.; engine-room expenses (B), £1,106. 8s.; total, £5,809. 1s.—*i.e.*, £1,000 less. This brings out the cost per unit as 3·5d., instead of 4·1d. According to these corrected figures, the advantages of his sixth scheme are not so apparent as he makes out by his figures.—Yours, &c., FRANCIS G. BAILY.

Maryon Park-road, Charlton, Kent.

ELECTRO-MAGNETIC INDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I regret to again have to trespass on your space, but your remarks on my letter of last week seem to call for some brief reply.

You will, I am sure, see that the question of leakage is one which concerns transformers *in particular* and not in *general*. The action of the iron in transformers in general is the subject of our research; consequently, we cannot deal with leakage at the present stage.

As I have stated in my Paper, the chief point of our method is this,—that we try to imitate as closely as possible the action of the current in a transformer; and I submit that any impartial critic will acknowledge that our method must bring us nearer the conditions of the cycle, and therefore nearer the true **B H** curve of the transformer, than any method hitherto published. The only limits to the rapidity with which the induction change can be measured after a change in the current are the self-induction of the primary circuit and the period of the galvanometer.

The curves given in my Paper show plainly, to all who will study them, the vast importance of this instantaneous measurement, and the errors that may be produced by stopping at points on the curves other than the ends; and they therefore supply the strongest evidence in support of the method which we deduced from *a priori* reasoning.

As for our misuse of the word induction, "What's in a name," so long as we make ourselves understood? We do not want anyone to follow us in our nomenclature; I merely introduced it in my Paper because I am used to it; and to say, for instance, "change of magnetisation," where I mean "change of B," seems unnatural to me. We have always said "change of induction," and I do not think we are alone in using "induction" in that sense.—Yours, &c.,

ERNEST B. VIGNOLES.

Woodfield Works, Harrow-road, W., May 26, 1891.

TWISTED TELEPHONE LINES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: To deal with all the inaccurate deductions of Mr. Bennett's last letter would occupy too much of your valuable space, so I will only draw attention to his admission that "noise can be found on 10 mile loops if specially listened for," which is hardly in accordance with the object and contention of his first letter.

I cannot but remark that Mr. Bennett appears to rely somewhat too much on the relation of his unfortunate experiences with twisted lines, "beyond his control," to support him in this discussion. I think it is at least premature to condemn a system, which has and is doing good work, upon such indefinite grounds.—Yours, &c., J. W. ULLETT.

TRADE NOTES AND NOTICES.

Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.]

In the course of a few days "The Electrician" Company will publish "THE ELECTRICIAN" PRIMERS in two volumes, price per volume 2s. paper covers, 2s. 6d. cloth.

TENDERS WANTED.—As will be seen by our advertisement columns, the Cleckheaton Local Board are prepared to receive tenders for lighting the Town Hall with electricity. Specifications may be seen at the Local Board offices, and tenders are to be sent to Mr. J. Armitage, the clerk, before Tuesday, June 9th.

MESSRS. CUTTRISS, WALLIS AND COMPANY (LIMITED).—We are in receipt of the new catalogue published by this firm, which contains particulars and prices of a number of their manufactures, including the "Eclipse" and "Improved Ring" dynamos, the "Alliance" and "Volt" dynamos and motors, a dynamo specially constructed for students, a dental dynamo, a small motor and fan, batteries, Cuttriss' calculating discs, &c. Included in the catalogue are several flattering testimonials from users of Messrs. Cuttriss, Wallis and Company's machines.

THE WHITEHALL DYNAMO AND MOTOR.—Messrs. Easton and Anderson have issued a circular describing their dynamos (Prentice's patent). Eight sizes are made, all parts of the same size being interchangeable. It is probable that if dynamo building were more widely taken up by such well-established firms we should see less of the clumsy and amateur-looking machines which are offered to the public by "electrical engineers and manufacturers."

ELECTRIC CRANES.—Messrs. R. Bolton and Co. have issued an illustrated list of electric travellers, winches, cranes, and derricks. The feature of these cranes is a triple gear, consisting of two winding barrels of different diameters. To these the two ends of the lifting rope are attached. The barrels may be separately or simultaneously clutched to the motor, thus allowing three different speeds to be obtained while the motor runs at a constant speed in one direction. The loads are given against the different sizes, but the speed of lifting is not stated.

ELECTRIC LIGHT PILLARS.—Messrs. W. Macfarlane and Co. have sent us their illustrated price list of lamp posts and ornamental brackets for street lighting, together with other very decorative pillars of a smaller size for use in large buildings, &c.

MESSRS. W. H. WILLCOX AND COMPANY.—This firm notify us that they have extended their premises by taking the warehouse adjoining No. 36, Southwark-street, which will give them greater facilities for dispatching orders received, and will enable them to hold a much heavier and more assorted stock of lubricating and cylinder oils, engineers' tools, and general stores.

MESSRS. ANDERSON, CAMPBELL, AND MUNRO (LIMITED), (IN LIQUIDATION).—A meeting will be held at Mr. David Strathie's, 162, St. Vincent-street, Glasgow, on June 22nd, at 12, for the account of the winding-up.

BUSINESS AMALGAMATION.—We are informed that Bernstein's Electricitätswerke Kommandit-Gesellschaft, of Hamburg, have amalgamated with the Allgemeine Electricitäts Gesellschaft, of Berlin, and that a new company will be formed in the latter city.

COMPANIES' MEETINGS & REPORTS.

The Consolidated Telephone Construction and Maintenance Company (Limited).

The tenth annual ordinary general meeting of the Consolidated Telephone Construction and Maintenance Company (Limited) was held at the Terminus Hotel, Cannon-street, yesterday, Mr. C. L. W. FitzGerald presiding.

The SECRETARY read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen, as you will observe from the report that we have presented to you, you will see that the profit for the year amounted to the sum of £11,573. 8s. 9d., which, with the amount brought forward from last year, leaves a balance to dispose of amounting to £13,416. 6s. 8d. The Board propose that we should pay a further dividend of 7 per cent. for the half-year on the ordinary shares, and 6 per cent. on the preference shares. This will make a dividend for the entire year of 6 per cent. for both descriptions of shares, £530. 3s. being written off for depreciation of plant and machinery, £63. 16s. 8d. for the cost of the new building, and the sum of £436 for goodwill, patent rights, &c. Now, gentlemen, in turning to the other figures, the first item that I will call your attention to is one that, of course, we look very much after, and that is the profit on manufacturing. The profit this year from that source is less by £253 than it was last year. I think, however, that if we consider everything that is not a bad result. Wages have increased, as also has the price of coal. In fact, the cost of all the materials pretty well that we use have increased, and yet we have come out with a loss of only £253. On the other hand, you will see that we received more in dividend from some of our subsidiary companies, and interest to the extent of £534, and this despite the fact that we have received only £50 from the River Plate investment, as against £250. On the debit side we find that our expenses have risen a little. The auditors' remuneration, if you recollect, we increased last year, and the travelling expenses have advanced slightly. The total increase on the four items under the head of general management, &c., comes to £135, and when I come to add up the entire outlay for the year I find that we have expended only £40 more than we did during the previous twelve months. I think that this may be considered very satisfactory. Coming to the balance-sheet, you will see that our plant and machinery are now valued at, I think, £520 less than they were last year, and this, I should tell you, notwithstanding that we have added very considerably to the plant by getting some very fine new machinery. I think I can safely say that the Company's plant was never more efficient than it is at the present moment. I am now engaged with the officials of the Company in reorganising the entire plant, in order to enable us to turn out more goods, as I found that, since December 9th last, which you will see by the report was the date at which one of the patents held by the National Telephone Company expired, there was an increase of business, and, therefore, we had to do something at the factory to enable us to keep pace with the demand upon us. You will see a little lower down that our stock comes to the sum of £6,895. 16s. That stock, I am happy to state, has decreased since last year. That means to say, of course, that we have not got so much stock on hand as we had last year. Of course, this was to a certain extent inevitable, because we have sold more of our manufactures which were completed instruments. Still lower down, you will see that the subsidiary and other companies owe us the sum total of £8,993. 3s. 5d.; while, on the other side of the balance-sheet, you will find that we owe only £1,669. 8s. 10d. I think that that is a very satisfactory feature of the report. I now come to the investments. As you are aware, this year we have not asked the shareholders to subscribe for any money in the form of preference shares. The two previous years we did. In the first of these we asked for £15,000, and in the second for £10,000. This year we have asked for nothing, but we have added to our investments. We have increased by no less a sum than £10,500 Anglo-Portuguese Telephone Company's debentures, and added £4,000 to the preference shares of the Telephone Company of Austria. Now, I should like to say a word—I was in hopes that Mr. Griffiths, our auditor, would be here to explain the matter, but he has not come—on the subject of two of your investments. The auditors have called the attention of the Board to the fact that some of the securities held by the Company have depreciated in value during the year. The Directors are of opinion that this depreciation may be only of a temporary nature; but should this view prove incorrect, it will, no doubt, be advisable to form a fund against this depreciation. Now, gentlemen, these two items refer to the National Telephone Company of London, and the River Plate Telephone Company of Buenos Ayres. I will take the latter first. The depreciation of this security is not owing to the business of that Company being bad, but to the fact that, by reason of the difficulties in which the Argentine Republic has been placed, and the enormous premium on gold, that Company cannot remit to this country the money it earns there in sufficient amount in order to pay us a dividend. The National Telephone Company, to my certain knowledge, is doing a bigger business than it ever did, and I know that it will pay us a good dividend; in fact, I know that it is going to give us a return almost directly. The lawsuit in Belgium seems to go on dragging its way along. It seems to me, indeed, that all law suits go on in that sort of way. Whether we are any nearer a decision I do not know, but we hope we are. I now come to the subsidiary companies, which I regard as a most gratifying item. These companies increase steadily year by year. This year the Telephone Company of Austria and the Anglo-Portuguese Telephone Company have increased in subscribers 564, representing an augmentation in the amount of revenue of £3,626. The previous year, I think, the increase was only about £50 more. I do not think I have anything more to say to you. I do not like prophesying, but I must say that I think the outlook of the Company is very good. Personally, I am very pleased with this balance-sheet, and all that I can say for myself and the Board is that, being very largely interested in the Company, we shall try to do our best to keep it in a satisfactory position, and to give you, if possible, increased dividends. I now beg to move,—

"That the annual statement of accounts and balance-sheet, and the report of the Directors as now submitted, be received and adopted."

Of course, if anybody would like to ask any questions, I shall be most happy to answer them to the best of my ability.

Sir ALEXANDER ARMSTRONG seconded the motion, which was carried unanimously without discussion.

On the motion of the CHAIRMAN, seconded by Mr. RICHARD VANZELLER, the retiring Directors, Sir Alexander Armstrong and Mr. Arthur Henry Baker, were unanimously re elected to their seats at the Board.

The auditors, Messrs. John G. Griffiths and Mr. Arthur Green were afterwards reappointed *nem. con.*

A SHAREHOLDER asked the Chairman whether he considered the patent rights of the subsidiary companies of any value?

The CHAIRMAN: Oh, certainly. We have never, from the commencement of the Company, taken them into our balance-sheet, but they are really increasing in value every day.

The SHAREHOLDER asked whether they were of marketable value?

The CHAIRMAN: I cannot say that.

The SHAREHOLDER: Could you get anything for them?

The CHAIRMAN: Oh, yes, we could. I should be very happy to give something for them.

Mr. BUCKINHAM said it would be remembered that in 1884 a committee of investigation was appointed by the shareholders. The result was that the then Directors felt it more or less their duty to vacate their seats, and others were appointed in their place. From that time to this the Company had gone on slowly but surely prospering. At all events, he for one, as an original shareholder of the Company, was very much more satisfied with its prospects than ever he was before. The Directors at that time, as well as the committee, very earnestly wished that he should join the Board, but unfortunately he was not able to do so. But three or four years ago they did him the honour to renew their request, and he consented to join them. When he did so, he found that there were certain actions on the part of the old Directors of the Company pending, all of which he was happy to say had been very satisfactorily settled. The last action was not commenced until four years after the committee had issued their report. In consequence of certain phrases which appeared in it, and which gave displeasure to one of the old Directors. It kept hanging over them until 1890, when he, who had always an aversion to law, which it was always advisable to avoid having recourse to if possible, advised his colleagues to compromise the matter. This they agreed to do, and the action was settled out of court. Knowing the amount of labour and trouble which the Directors had had to get over all those difficulties, and knowing the amount of influence which Mr. FitzGerald had brought to bear on the Company—and without that gentleman's efforts he was bound to say that he did not know how the Company could have existed up to the present time—he had very much pleasure in proposing the following resolution, which he was sure would meet with acceptance on the part of the shareholders:—

"That, having regard to the special services rendered to the Company by Mr. C. L. W. FitzGerald, Mr. Henry Grewing, and Mr. Arthur Henry Baker" (the three Directors against whom the action was brought) "as members of the Committee of Investigation, and the expenses consequently incurred by them, this meeting votes them a payment, by way of reimbursing them, of a sum not to exceed £600."

Mr. R. E. BATEMAN said that, although this was the first time he had heard of this proposal, he had the greatest pleasure in seconding the motion, and in recommending his fellow shareholders to give it their support. He would not use any expressions reflecting on the former members of the Board, but when the shareholders took into their consideration the way in which the three gentlemen named in the resolution had managed and improved the value of their property, he did not think they could do otherwise than approve the resolution.

Mr. S. C. BUCK supported the motion, remarking, that, but for Mr. FitzGerald and his other two colleagues, the shares of the Company would not now be worth sixpence.

The SOLICITOR, referring to the last of the actions brought against the Company, said that, as their legal adviser, he strongly felt in 1890, when their affairs were in a fair way to go on prospering, that it would be to their great disadvantage if the whole of the past history of the Company had to be raked up in a court of law, notwithstanding that the three gentlemen against whom the action was brought were perfectly prepared, having a clear conscience, and having at all times acted *bona fide* in the interests of the shareholders, to go into court; and, consequently, he brought pressure to bear upon them, in the interest of all parties, to terminate the matter by the compromise that had been happily arrived at.

The resolution was carried unanimously.

The CHAIRMAN briefly returned thanks on behalf of himself and colleagues, assuring the meeting that it would be their earnest endeavour in the future, as in the past, to do all they could to promote the prosperity of the Company.

Before separating, the shareholders were invited to inspect several specimens of the Company's manufactures, which were on view in the room.

Digitized by Google

The Indo-European Telegraph Company (Limited).

An extraordinary general meeting of the members of this Company was held at the offices, Old Broad-street, last Monday, under the presidency of Mr. J. H. Tritton, when the following resolution, duly passed by the requisite majority at the ordinary general meeting of the Company, held on April 28th last, was submitted for confirmation as a special resolution :—

"*That in addition to the regulations of the Company, as contained in the Articles of Association, the following new regulation (to be numbered* 116a) *be adopted, that is to say—*

"*That the present Managing Director of the Company shall be a member of the Board, having all the privileges and being subject to all the obligations of an ordinary Director, except that he shall not receive extra remuneration as a Director, nor shall he retire from office by rotation. If the Directors think fit, this provision shall apply to any future Managing Director whom they may appoint.*

"*The other regulations of the Company shall be treated as qualified so as to give full effect to this new regulation.*"

The MANAGING DIRECTOR (Mr. W. Andrews) having read the notice convening the meeting, as above,

The CHAIRMAN said: Gentlemen, I declare the meeting to be duly constituted. It is a special meeting, called in accordance with the articles of association, in order that the resolution which has been read to you, and which was submitted to our ordinary general meeting, may be placed before you for consideration, and, if you think fit, for confirmation. Having read the resolution as above, he said: I have great pleasure in moving that the resolution be approved and confirmed.

Mr. WEAVER having formally seconded the motion,

The CHAIRMAN submitted it in the usual manner, and declared it carried.

The proceedings then terminated.

The City of London Electric Lighting (Pioneer) Company (Limited).

The first ordinary general meeting of this Company was held at Winchester House, Old Broad-street, E.C., on Monday, the 25th instant. The notice stated :—"This being merely the formal statutory meeting (in accordance with the requirements of the Companies' Act), there will be no business to be transacted. The Directors, however, take this opportunity of informing the shareholders that suitable sites have been secured for the central generating stations by the contractors, and that good progress has been made by them with the necessary buildings, machinery, and mains, and that it is hoped that the first portion of the public lighting in Queen Victoria-street will be completed by June 1st. In order to be prepared to meet any claims for work done and certified as satisfactory by their consulting engineer, the Board consider it advisable to call up the balance of the capital at an early date, due notice of which will be given."

The Lord Mayor presided.

Mr. J. CECIL BULL (the Secretary) read the notice calling the meeting as above.

The CHAIRMAN said: Gentlemen, you have heard by the notice which the secretary has read that this is merely a statutory meeting, which is obliged to be held within four months of the registration of the Company, in accordance with the requirements of the Joint Stock Companies Acts; but doubtless the shareholders will be anxious to learn what we have done during these four months. You will be glad to hear that, notwithstanding the great financial depression and difficulty at the time, we were enabled to launch this Company most satisfactorily. The capital was applied for nearly three times over, and we were enabled to arrange for the issue of the Company upon the most economical terms. There has been some misconception in the minds of many people as to the duties and the scope of the Pioneer Company, and I should like to point out that the object of the Pioneer Company, as stated in the prospectus, was not to take over the Provisional Orders and contracts, but to initiate the supply of electricity by providing the contractors with funds by enabling those contractors, after they had obtained the concessions from the Commissioners of Sewers, and the authority of the Board of Trade, to proceed with the work which they had undertaken, the right being reserved to launch at some future time a larger company to take over the concessions which had been secured. I should like to mention that in our early days we summoned some of the leading electricians to meet the Directors, and several meetings were held, and were very largely attended. The object of these meetings was to decide which were the best means and methods for lighting the City of London, and it was most satisfactory that the authorities upon electric lighting in this kingdom who were summoned were unanimously of the opinion that the system which the Board have since adopted was the best suited for our requirements, and this was why we decided to carry their recommendation into effect; and we feel certain that when the electric lighting of the City of London is completed we shall have a city lighted in a way which will be second to no other city in the world. It will be a matter of satisfaction to you to know that we have secured most suitable sites for placing our machinery. That for the eastern district of the City has been secured near Tower Hill, and for the central and western districts on Bankside. The Directors thought it advisable while the streets were being taken up to lay down the necessary conduits for the electric lighting, already agreed upon, to take the opportunity of laying down additional conduits in order that the streets may not be disturbed again, because that is, of course, always a matter of considerable annoyance whenever it is done. The Board of the Pioneer Company during the four months that it has been in existence has been doing a great deal of preparatory work in order to assist in every way possible the new company which is proposed to be started at no distant period, and we have been getting out statistics, with the help of our consulting engineer, and making numerous other preparations, such as deciding upon the routes for the conduits and mains, making various plans of the several districts of the City, schedules of prices, and so on, all of which will be of great use to the Board of the new company, and enable them to arrive at a satisfactory estimate with regard to the work which they will be called upon to undertake. I might also mention that the work of one firm of contractors is so far advanced that we hope that Queen Victoria-street will be lighted by electricity about the middle of next month. The larger Company (which will, as I mentioned in the earlier part of my remarks, be entitled to take over the contractors concessions, which have been obtained from the Commissioners of Sewers with the sanction of the Board of Trade) will, we hope, be arranged within a comparatively short period, and the formation of that Company is now in the hands of men of such very high standing and undoubted reputation, that I feel confident it will eventually return not only a fair remuneration to the shareholders, but also secure for the City of London the most perfect and unique system of electric lighting. We, for our part, have taken the greatest possible care in reference to every small detail; even the construction of the lamps and various other minor matters have received the most careful attention of the Board of Directors, and I can assure you, speaking not only as Chairman of this Company, but as Lord Mayor of the City of London, that I am entirely satisfied with the work that the contractors have done as yet. I have no resolution to put to the meeting, but I shall be happy to answer any questions that any of the shareholders desire to ask.

Mr. EDWARD LEE said that he wished to suggest that in the event of further capital being required, that capital should not be raised by calling up the present uncalled amount of the shares, as hinted in the notice calling the meeting, because he considered that their uncalled capital was their strength, and if further capital was required, he should suggest that it should be obtained by the issue of additional capital. He felt perfectly satisfied, after the remarks that they had listened to from the Lord Mayor, that all the shareholders would be willing to take up whatever new shares might be required. He was very much gratified at the statement of the Chairman and with the ability with which everything appeared to be conducted.

No further questions were asked.

The LORD MAYOR, in reply, said that if it should become necessary as far as the Pioneer Company was concerned to call up more capital it would only be required for a very short period, because the new company which was to be formed would purchase what the Pioneer Company had done, and therefore the shareholders in the Pioneer Company would be enabled either to take shares in the new company or to have their money returned, just as they pleased. The interest of the Directors of the Pioneer Company was the interest of the shareholders of that company, and the matter of the new company would be entirely one for the shareholders to consider for themselves, and for each one to do what he deemed best in his own interest.

Mr. LEE said that his only reason for raising the point was whether the amount of capital that the Company now possessed would be sufficient for carrying on the works until such time as a new company was formed.

The LORD MAYOR: We think so. We think it is ample. If any other gentleman has any question to ask I shall be happy to answer him. (A pause.) Unless any gentleman has any question to put, that really concludes our meeting to-day, because there is nothing—no business—before the shareholders, as this is only a statutory meeting which we are compelled to hold.

Mr. S. MACLEAY said before they separated he begged to propose a vote of thanks to the Right Hon. the Lord Mayor for presiding, and to the Board of Directors who appeared to have done all in their power to further the interest of the Company.

Mr. HEPBURN seconded the motion, which was carried.

The LORD MAYOR, in reply, said that, on behalf of his colleagues and himself, he must say that they appreciated very much indeed the vote of thanks which had been kindly accorded to them. Their one desire was to do their utmost to make the electric lighting of the City of London as perfect as it could possibly be, and he thought that they might feel satisfied that in the Pioneer Company, and he believed he might also say confidently in the larger company to be formed, the shareholders would find they had a very sound investment.

The proceedings then terminated.

Birmingham Electric Supply Company (Limited).

The first annual meeting of the shareholders of this Company was held on Tuesday, at their offices in Dale End, Birmingham; Mr. Henry Buckley in the chair.

The following is the report of the Directors :—"The Directors are glad to be able to announce that the works of the supply station and the mains through a considerable portion of your area are complete and in working order. The works were formally opened by the Mayor (Mr. Alderman Clayton) on April 22, 1891. The demand for the light has been most satisfactory, and the works start on a system of 2,580 16 c.p. lamps. These lights are distributed amongst various offices and shops representing some of the most important professional and trade interests in the city, one of the first customers being the Corporation of Birmingham, with whom arrangements are made for the lighting of the Victoria Courts. In the purchase of the land and the laying out of the works and mains it has been necessary to provide for not only the present but for the future demand for the light—*i.e.*, the available land is sufficient for a station estimated to

Digitized by Google

provide 25,000 16 c.p. lamps, and a chimney stack has been built large enough for this. The engine-house and boiler-shed will be sufficient for half this number, and for the immediate supply engines and boilers have been fixed for 5,000 lamps. Mains have now been laid through the most important streets within the Company's area, and current may be obtained along 7,000 yards of street frontages. The Company have been fortunate in securing a substantial tenant for a portion of the offices which will not at present be required."

The CHAIRMAN, in moving the adoption of the report, said he had not a great deal to add to what he said at the recent opening of the Company's works. The orders were coming in very satisfactorily. Up to the present they had received orders for 2,639 lamps, but when they saw that such orders were spread over only 42 customers it showed the shareholders what a good opening there was for the extension of their trade in the city. Bearing this in mind, the Directors had resolved to issue the balance of the shares in the first instance amongst the shareholders. This would enable them to cope with additions to plant that the extension of business will demand, and he was glad to inform them that, considering the broken holiday week, the shares had been well taken up. The Chairman went on speaking of the question of dividend. He thought he was justified in the statement that with the present year they would be able to pay the entire working expenses, and, if that turned out as he expected, at the end of 1892 there was reasonable expectation for them to pay a dividend. But that must depend upon the earning power of the Company in Birmingham and the number of lamps applied for, and, judging by the experience of other electric companies, he believed they would be making a profit from 1892.

The report was adopted.

Mr. G. S. Albright and Mr. Buckley, the retiring Directors, having been re-elected, and the auditors (Messrs. Sharp, Parsons and Co.) having been reappointed, the meeting separated.

Notting Hill Electric Lighting Company (Limited).

The following is the Directors' report, to be presented at the fourth ordinary general meeting, to be held at the Central Electric Light Station, Bulmer-place, Notting Hill-gate, London, W., on Saturday, May 30th, at 4 p.m.:—

The Directors beg to submit herewith the accounts of the Company to December 31, 1890. It will be observed that the expenditure on capital account covers a period of nearly three years, from February 21, 1888 (the date of incorporation of the Company), to December 31, 1890. As, however, before the publication of the prospectus in January, 1890, no shares were issued beyond a few originally subscribed for and paid up in full by the founders of the Company, the bulk of the expenditure on the works has been incurred during a period of less than twelve months. On December 31, 1890, the capital paid up was £42,676, and the liability on the shares issued amounted to £27,444, and there remained £29,980 of unissued capital. Altogether 7,002 shares have been subscribed, and a special settlement was obtained on the Stock Exchange on July 1, 1890, for the 6,318 ordinary shares of £10 each, which were applied for and allotted in accordance with the prospectus, and an application has been lodged with the Stock Exchange Committee for a quotation of these shares upon the official list. The capital expenditure, as shown by the accounts, amounted at the end of the year to £43,126. 5s. 2d., but this sum does not include the further liabilities on contracts entered into for construction of buildings, mains, and machinery, since nearly completed. These amount to about £12,000, bringing the total expenditure incurred and contracted for before the date of the opening of the works to about £55,500.

Subsequent to the purchase of the lease of the property for a central station in Victoria Gardens, Notting Hill, which is referred to in the prospectus, the Directors took the opportunity which offered itself of acquiring the freehold. It also became necessary, owing to injunctions which were obtained during the construction of the central station by the owners of neighbouring property, to purchase the lease of seven small houses adjoining in Bulmer Place. These houses are all let.

Considerable delay occurred in the completion of the works, owing, in the first place, to the injunctions above mentioned, and when the work could have been resumed the very severe weather supervened, thus making it impossible for the contractors to proceed for a considerable time with the building of the central station. The Directors are, however, glad to state that the central station has been now completed, and the Company is able to supply the electric current to houses situated in the principal streets of the northern and central portion of the area of supply, in which the mains have already been fixed.

The number of houses in the district which are prepared to take the light is continually increasing. Already the owners of 70 houses have notified their readiness to take the lght. This number includes Holland House, and it is estimated that at the present time the installations comprise a total number of about 4,000 lamps, reduced as usual to 8 c.p. The engineers have reason to believe that a considerable number of householders are intending to have their houses wired as soon as the current is actually being delivered, and it is expected that before next winter the generation of the amount of electrical current supplied to customers will profitably occupy the whole of the existing plant.

Much difficulty has been experienced in obtaining a site for a second central station, but a provisional contract has now been entered into in reference to a site which the Directors consider well suited for the purpose, and, as soon as the agreement is completed, steps will be taken to lay the mains in the southern part of the district, when the whole of the parliamentary area granted to the Company can be supplied with the electric current. In this southern district an increase in the number of customers is to be expected, in consequence of the decision of Lord Ilchester to let for building purposes about 2½ acres of Holland Park.

The Directors who retire are Messrs. A. Howden and J. T. Jarvis, who, being eligible, offer themselves for re-election. The auditors, Messrs. Deloitte, Dever Griffiths & Co., retire, and being eligible, offer themselves for re-election.

NEW COMPANIES REGISTERED.

ARC ACCUMULATOR COMPANY (LIMITED).—Registered by Sydney Morse, 4, Fenchurch-avenue, E.C., with a capital of £1,000, in £1 shares. Object: To carry on in the United Kingdom the business of electricians, electrical engineers, &c.

CLEGG'S METAL INCANDESCENT LAMP COMPANY OF FRANCE (LIMITED).—Registered by Bircham and Co., 46, Parliament-street, S.W., with a capital of £10,000, in £10 shares. Object: to carry into effect an agreement, made May 13, between James Clegg of the first part, Betts and Co., Limited, of the second part, and this Company of the third part, for the acquisition of certain inventions and patents relating to electric lamps and other electrical appliances, and to develop and work the same. There shall not be less than three nor more than eight Directors. The first are Archibald Campbell, Charles Cheswright, sen., James Clegg, Allan Maclean, Charles Cheswright, jun., Leveson Dudley Ryder, and Henry Tyler Cheswright. Qualification not specified. Remuneration: Ordinary Directors, £350, divisible; Managing Director's remuneration to be determined in general meeting.

FOREIGN AND COLONIAL ARC ACCUMULATOR COMPANY (LIMITED). Registered by Sydney Morse, 4, Fenchurch-avenue, E.C., with a capital of £1,000, in £1 shares. Object: to carry on elsewhere than in the United Kingdom the business of electrical engineers, &c.

WOODFIELD SYNDICATE (LIMITED).—Registered by Maynard Carter, with a capital of £12,000, in £1 shares. Object: to carry on the business of an electrical engineer in all its branches in Great Britain or any other part of the world. There shall not be less than two nor more than five Directors; the first are to be appointed by the subscribers to the memorandum of association. Qualification, being a shareholder. Remuneration to be determined in general meeting.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the past week amounted to £4,730.

CITY AND SOUTH LONDON RAILWAY COMPANY.—The traffic receipts of this Company for the past week amounted to £768.

COMPAGNIE FRANCAISE DU TELEGRAPHE DE PARIS A NEW YORK. At a meeting of this Company held at Paris, it was decided that an emission should be made of sufficient bonds to raise the capital to 12,000,000f.

COMMERCIAL CABLE COMPANY.—The Stock Exchange Committee have ordered the further issue of $500,000 stock to be quoted in the Official List.

INDIA-RUBBER ESTATES COMPANY.—Under a winding-up order, made against this Company on the 11th ult., a summary of the statement of affairs has now been issued by Mr. Stewart, the Official Receiver. The liabilities amount to £3,662, and an estimated surplus of £2,033 is disclosed. The Company was registered on July 2, 1890, and was formed for the purpose of acquiring and working a concession from the Government of the Republic of Liberia for the sole right of collecting and exporting india-rubber and gutta-percha from the said Republic for the European and American markets. The nominal capital of the Company is £225,000, in £1 shares, of which 132,024 have been allotted. There are 120 shareholders. The purchase-money originally agreed upon was £155,000, but appears to have been subsequently reduced to £144,000, of which a balance of £20,000 is unsatisfied. The insolvency of the Company is attributed generally to the inability of the Directors to obtain from certain shareholders a sufficient portion of the unpaid calls to complete the purchase of the concession, which has never come into the Company's possession. Mr. Stewart observes that the whole circumstances connected with the payment of the purchase-money would appear to require further investigation. As regards contributories a deficiency of £129,990 is disclosed. It is stated that a scheme of reconstruction is likely to be proposed.

RICHARD HORNSBY AND SONS (LIMITED).—The Directors have declared a dividend for the past half-year of 3s. 3d. per share.

RUSTON, PROCTOR, AND COMPANY (LIMITED).—The second annual general meeting was held at the Cannon street Hotel, on Tuesday, under the presidency of Mr. Joseph Ruston, when a dividend was declared of 10s. per share, free of income-tax, making, with the interim dividend of 5s. per share paid on November 1st last, a total dividend of 7½ per cent. for the year.

SPANISH NATIONAL SUBMARINE TELEGRAPH COMPANY (LIMITED).—The numbers are announced of 81 Six per Cent. Mortgage Debentures, amounting to £8,100, to be paid off at par on or after June 30th next.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended May 22, 1891, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,803.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this Company for the two weeks ended May 15th amounted to £3,116, as compared with £3,270 for the corresponding period last year, showing a decrease of £154.

THE NON-CONDUCTOR OF ELECTRICITY.

WAREHOUSE.

VULCANISED FIBRE,
PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 2ft. 6in., varying in thickness from 1-50in. to 1in.

FACTORY.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.

MOSSES & MITCHELL, 70, Chiswell-st., London, E.C.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 681.—Vol. XXVII. FRIDAY, JUNE 5, 1891. Price Fourpence.

NOTES.

A commencement will probably be made early next week with the electric lighting of the City, when some five-and-twenty lamps in Queen Victoria-street will be lighted from the Brush Company's temporary station at Bankside. The first instalment of the public lighting plant is now in position, and comprises two 250 H.P. Babcock and Wilcox boilers, and two 40-light Brush machines, rope driven by Raworth engines. As soon as the arc lighting has been started, two 100 kilowatt Mordey alternators and the necessary engine power will be installed for the purposes of private lighting. The permanent station and generating plant are as yet quite *in futuro*, but the ultimate capacity of the Bankside plant will be sixteen 40-lighters and alternators having an aggregate output of 3,000,000 watts; the largest units being 400 kilowatt, and the smallest 100 kilowatt machines. Raworth engines and Babcock and Wilcox boilers will be used throughout, and condensing plant will be erected. We trust that the natural eagerness of the contractors to make a beginning will not result in any untoward mishaps.

On the strength of forty years' experience of coke making, Mr. Steavenson writes to the *Journal of Gas Lighting* to criticise the Presidential Address of Mr. Trewby before the Incorporated Institution of Gas Engineers. With regard to transmission of power, he says that he has found "electricians in such matters very slippery customers," and proceeds to deal in a confused way with "commercial efficiency" and brake horse-power, and says he has "yet to learn of any electrical plant which reaches 50 per cent. in brake horse-power, compared with the indicated horse-power of the engine." Why electrical transmission should be debited with the difference between the brake horse-power and the indicated horse-power of the engine, he does not attempt to explain. With an innocent *non sequitur* he adds, "whereas with gas engines there are well-authenticated cases of 20 cubic feet supplying an actual brake horse-power, which is a very different thing from 'generating an electrical unit'—possibly in the dynamo only." The discussion on a recent Paper "On Electrical Mining Machinery" confirmed our view that electrical engineers are, as a rule, the only ones who really know what efficiency means; and, we would add, that until electrical engineers had shown how to do it, no one had ever measured a horse-power with any approach to accuracy. Unless in the hands of exceptionally skilled engineers, the indicator will not compare for accurate results with the most rubbishy German ammeter or voltmeter. And, lastly, we assert that for high efficiency, and the accuracy with which that efficiency is measured, there is no class of machinery that can compare with the modern dynamo.

While glancing recently at an able Paper on that, to naval minds, engrossing subject of ships *versus* forts, we were glad to find that the author was of opinion that a little less expenditure on big guns and a little more on large search lights would be distinctly advantageous; and the reader was asked to imagine the utter bewilderment of the captain of an ironclad endeavouring to force a narrow passage at night-time in the glare of half-a-dozen well-handled projectors. An involuntary testimony to the value of the search light as a means of defence was, indeed, given but a few weeks since by the loss at Cherbourg of the torpedo-boat "Edmond-Fontaine," which was cut in two by a cruiser whose captain was dazzled by the rays of a search light.

Some little time ago we referred to some facts, published by Mr. F. J. Smith in the *Philosophical Magazine*, concerning the slowness with which small electro-magnets lose their magnetism, after the magnetising current had ceased. In the January number of the same magazine appeared a further communication on this subject, and an apparatus was described for detecting the latency, or the time taken for the magnetism to subside. This time, it seems, can be detected to $\frac{1}{20000}$ of a second; and, although few results are given, it appears that in one experiment a certain iron bar took 0·015 second to lose its magnetism. This time effect is rather important, as it must occur with large magnets as well as small ones, and will take place whenever the magnetising current changes in magnitude. In the field-magnets of dynamos, where the magnetic circuit is very good, we may expect it to be more important still, and may hence prove a difficulty when it is desirable to make the field respond readily to the changes of current strength. The running of large compound dynamos in parallel is sometimes rendered difficult by the slow response of the iron to the magnetising forces, as was pointed out recently in our correspondence columns by Mr. Brew (*The Electrician*, January 2, 1891); and although the greater part of the effect he described is to be sought in the large time constant which the shunt coils of such machines possess, some of it may be due to another cause.

A new determination of "v," the ratio of the electro-magnetic to the electrostatic units, has been recently announced by

Digitized by Google

M. PELLAT in the *Comptes Rendus*. The method employed was similar in several respects to one used a year or so ago by Sir WILLIAM THOMSON. A potential difference was measured electrostatically by means of a Thomson absolute electrometer, and electro-magnetically by balancing a known fraction of the voltage against a battery of 13 Latimer Clark cells, the latter being afterwards standardised by passing a current through a known resistance, and an absolute electro-dynamometer, and comparing the voltage set up at the terminals of the resistance with the electromotive force of the cells. Two sets of determinations were made at potentials of 189 volts and 378 volts respectively, and a subdivided megohm was used to fraction down the voltage to that given by the battery of cells. The numbers obtained for "v" were $3{\cdot}0093 \times 10^{10}$ for the first set of experiments, and $3{\cdot}0091 \times 10^{10}$ for the second; and within the limits of experimental error these values are the same as that denoting the velocity of light.

WHILE M. PELLAT can be congratulated upon his skill and patience shown in obtaining so good a result, it is still somewhat open to question how frequently it is desirable in the interests of science to undertake these extremely difficult determinations. A result of this kind, only obtained after three years' careful work, and requiring the highest experimental skill, does not add appreciably to our knowledge. For several previous determinations have shown that the velocity of light, and the ratio of the electric units are represented on the C.G.S. system by the same number to a very close approximation; and until the electro-magnetic theory is further advanced, there is no special interest in finding out whether there is any minute difference between the two. The numbers obtained serve rather as an indication of the accuracy of the various experimenters than as a direct aid to scientific progress. The practical value of the number is very small, as the electrostatic system of units is never used. It would be quite different if the value of a material standard were in question, as for instance in the determination of the ohm. Here it was desirable to obtain the most accurate value possible, and time and skill spent upon the work have been well repaid; although, even in this case, now that the value of the new legal ohm has been finally settled by the Electrical Standardising Committee, it is doubtful whether it is worth while that fresh determinations should be made. The skill needed for them could be far better employed in other directions.

Sir W. Thomson.—To celebrate the admission of Sir. W. Thomson to the freedom and livery of the Clothworkers' Company a dinner was held at the Company's hall, on Wednesday evening, at which the new liveryman was present.

The Porto Rico Cable.—The laying of a cable between Spain and the island of Porto Rico is again under discussion. The Minister for Colonial Affairs has stated in the Cortes that he is considering the conditions on which to invite tenders.

Royal Institution.—At the general monthly meeting of this Institution, on Monday, June 1st, the special thanks of the members were returned to Mrs. Priestley for her donation of £21 to the fund for the promotion of experimental research.

The Telephone in Berlin.—The network of telephone cables already laid beneath the streets of Berlin is estimated to meet the requirements of 30,000 subscribers, the present total being 15,000, or more than the total for the whole of France.

Electrical Bills in Parliament.—On Tuesday last, the Earl of Morley's Committee on unopposed Bills passed the Bill to render valid letters patent to Messrs. Worms and Balé for an improved process and apparatus for tanning by the aid of electricity.

Telephone Trunk Wire Extensions in France.—The necessary money has been voted by the local authorities concerned for the erection of a telephone trunk wire between Paris, Nancy, and Epinal. Nancy is some 190 miles and Epinal some 225 miles from the capital.

Royal Society.—Among the Papers down for reading before the Royal Society yesterday were the following: Prof. O. J. Lodge, "Experiments on the Discharge of Leyden Jars"; Prof. Ayrton, Prof. Perry, and Dr. W. E. Sumpner, "Quadrant Electrometers."

The Berlin Telegraph School.—The course at the Berlin Telegraph School, intended for the instruction of superior officers, includes physics, chemistry, mechanics, mathematics, telegraph construction, commercial geography, commercial law, international law, finance, and political economy.

Eastern and South African Telegraph Company.—Advice has been received of the opening of a telegraph station at Fort Tuli, which is 600 miles north of Kimberley. The British South Africa Company have made arrangements to proceed without delay in continuing the line on to Fort Victoria and thence to Fort Salisbury.

Electrical Communication with Lighthouses.—At several shipping ports a movement has been set afoot in favour of electrical communication being established with the principal lighthouses along the coast. The President of the Board of Trade has consented to receive a deputation on the subject from the Associated Chambers of Commerce on the 12th of June.

Electric Launch on the Lake of Zurich.—The first electric boat on the Continent was launched last month on the Lake of Zürich. It has been built by Messrs. Esscher and Wyss and the Oerlikon firm. It attains a speed of 10 kilometres per hour, and can run five or six hours with one charge of the 56 secondary cells carried.

City and South London Railway.—The fares on this line will in future be—1d. fare up to 8 a.m. between King William-street and the Oval, to and from; and 1d. fare throughout the day from the Kennington, the Elephant and Castle, and the Borough Stations, except between 8 and 10 a.m. and on Sundays and Bank Holidays.

Domodossola.—*L'Elettricita* states that the electric lighting of the streets of Domodossola was inaugurated at the beginning of the present month. The installation, which has been put down by the Society for the Utilisation of Hydraulic Power, is on the series system, a current of 5 amperes at 2,000 volts pressure being generated at some falls on the river Bogna, a mile and a-half from the town.

The Tasmanian Exhibition.—The Tasmanian Exhibition Committee have advised the Agent-General in London that Mr. Pousty, electrical engineer, Launceston, is willing to act as agent for any English firm desiring to exhibit electrical apparatus in the Tasmanian Exhibition. The committee have every confidence in Mr. Pousty's ability as a practical electrician, and reference upon this point is permitted to Sir Edward Braddon, 5, Victoria-street, Westminster.

Telephonic Communication in Yorkshire.—From recent reports of the proceedings of the Leeds Chamber of Commerce, it appears that negotiations have been going on between the Telephone Exchange and the Mutual Telephone Company. An arrangement between the two Companies has now been effected, whereby the interest of the Telephone Exchange is to pass into the hands of the Mutual Company, and steps are at once to be taken by the latter to extend its system to the principal towns of Yorkshire.

Fuel Consumption in Steam Engines.—M. de Swarte has recently read a Paper before the Société Industrielle du Nord de la France, in which he gives an account of the investigations in which he has been engaged for some time, concerning the question whether there is a definite relation between the speed of the piston and the fuel consumption in steam engines. He

Digitized by Google

has reached the conclusion that such a relation exists, and that the consumption decreases at an increasing rate when the speed of the piston augments.

Liverpool Corporation Electrical Laboratory.—At a meeting of the Watch Committee of the Liverpool Corporation, on the 25th ult., the city engineer presented a list of candidates for the post of junior assistant to the electric inspector. Thirteen gentlemen had replied to the advertisement, and out of these three had been picked out. The committee unanimously decided to appoint Mr. J. A. Robertson, of Peterborough, to the post. This gentleman is one of Prof. Jamieson's students, and has had the advantage of a training in the laboratories of the Glasgow and West of Scotland Technical College.

Cable and Land Line Interruptions and Repairs.—

Line.	Date of Interruption. 1891.		Date of Repair. 1891.

* Not yet repaired.

Newcastle.—At a recent meeting of the Town Council a petition to Parliament against the Bill to confirm the Newcastle and District Electric Lighting Company's Provisional Order was presented on behalf of the Town Improvement Committee. It was stated that the principal objection to the Bill was that in its present form the Corporation would not be given the complete control of overhead wires. There would not be the slightest difficulty with the Company in coming to an agreement with the Corporation. The matter was really a fight between the Corporation and the Board of Trade. The Board of Trade wished to intrench upon the Corporation rights. The petition was unanimously ordered to be sealed.

Electric Lighting at Kassel.—The inauguration of the electric light at Kassel took place on the 24th ult. The central station in the town is furnished with power transmitted from turbines five miles distant. The alternating current is used for this transmission, but the alternating motor at the central station drives direct current dynamos, which supply the town on the 3-wire system. An accumulator battery of 100 H.P. has been put down by the Hagen Factory (formerly Müller and Einbeck). Messrs. Siemens and Halske have laid the conductors, and the Oerlikon firm have supplied the dynamos. The whole work has been carried out under the supervision of Herr O. von Müller, the originator of the scheme.

Electric Traction at Minneapolis and St. Paul.—In these two towns, which will shortly possess 230 miles of electric tramways, and which have already a tolerably large mileage, the steam trams, according to local accounts, have been improved out of existence. The *Tribune* of Minneapolis announces that "the steam roads between the two places have made up their minds to withdraw from competition with the electric line, which, though still so recent, has cut into their business to such an extent that nothing is left of it." In view of what has already been accomplished the Electric Street Railway Company is substituting for the 30 H.P. motors others of 50 H.P., which will also haul trailers; and, if necessary, trains will be started from each town every minute.

A Long Run.—In an affidavit, recently sworn before a public notary in the City of London, Mr. C. J. Hall, late manager of the House-to-House Company's station at West Brompton, gives some further particulars with regard to the long run of one of the dynamos at this station, which was alluded to in our issue of February 13th. A set of generating plant was started on the 28th of November last, at 3:45 p.m., and ran without intermission night and day until 9:30 a.m. on the 26th of December. The total length of run was 665¾ hours, the flywheel of the engine made 3,595,050 revolutions, the pulley of the dynamo 15,938,055 revolutions, and the field-magnets travelled a distance of 46,787 miles. The exact length of the run, without the rest of a single second, was 27 days 17¾ hours

An Effect of High Peripheral Velocity.—A Montreal correspondent of *Nature* communicates the following result of an experiment regarding the whirling of steel bands, about which there has recently been some controversy in that journal:—A weldless steel flash, with spherical body 12in. in diameter and ⅜in. thick, constructed for use in a centrifugal milk separator, to revolve about its axis of symmetry at a normal speed of 7,000 revolutions per minute, was whirled at a gradually increasing speed, with a view to ascertaining the "bursting" velocity. At 16,000 revolutions per minute the body of the flash had bulged 2in. in diameter. This is equivalent to an extension of 17 per cent., the peripheral speed being 840ft. per second (about 570 miles an hour), and the tension 31·5 tons per square inch. The experiment was not continued, as it was considered sufficiently satisfactory, and the bulged flash is kept as a curiosity.

The New York Subway Controversy.—Final action was taken last week, says the *Electrical World*, in its issue of May 28th, by the New York Board of Electrical Control in the contest which for years has been carried on between the opposing factions in the electrical world, represented on the one side by the combined electric lighting companies, and on the other by the Western Union Telegraph Company, the Metropolitan Telephone Company, the Edison Electric Company, and the Bell Company, resulting in a complete victory for the latter combination, which, under the title of the Empire City Subway Company, was awarded a privilege which practically will give it full control of all the subways hereafter to be built. The high-tension electric light companies, with a capital of $15,000,000, had been compelled by the exigencies of the occasion to unite for the first time in their history, while their opponents, especially the Metropolitan and Edison Companies, which already virtually own the old subway company, were equally determined.

The Electrical Utilisation of Water-Power.—An important work, says the *Electrical Engineer* of New York, has been undertaken by the South-Western Electric Light and Water-Power Company for the utilisation of water-power situated near Joplin, Mo., for electrical purposes. The scheme includes a fine natural water-power about 5½ miles from Joplin, and when the present installation is completed, will cause about 2,000 effective horse-power to be available. A large concrete dam has been constructed, and the turbines have been built by Leffel and Co., of Springfield, O. These turbines have 66in. wheels, and work under a head of 21ft. The electrical equipment consists of one 1,500-light 2,000 volt alternator and two 50-light arc machines. All the electrical machinery for this installation has been supplied by the Thomson-Houston Company.

Relative Cost of Various Modes of Traction.—A report issued by the United States Census Department has just been published, giving some statistics as to the relative cost in America of the various modes of traction. The report covers statistics of 50 tram lines, 10 of which are operated by cable, 10 by electricity, and 30 by animal power.

	Cable.	Electric.	Horse.
Total Cost of roads and equipment	$26,351,416	$2,426,285	$22,788,277
Cost per mile of road and equipment	$184,275	$36,094	$41,283
Total operating expenses per car mile	14·12 cents.	13·21 cents.	18·16 cents.

The Magdeburg Electrical Testing Establishment.—The electrical testing establishment, which has been in operation for nearly a year, has, says *Industries*, continued to be fully employed up to the present time. Like the association for the inspection of boilers, it undertakes to make for its members yearly inspections of electrical installations. In this way it has accomplished very useful work for the owners of electrical works. Its influence has been the more powerful in consequence of the fact that it is entirely independent of any electrical firm, and can therefore give an unbiassed opinion. The activity of this establishment is felt through-

Digitized by Google

out the whole of Germany. Its work consists in examining and reporting on the estimates for electrical installations. It affords advice and information concerning electrical apparatus, and gives its members, by means of circulars, the benefits of the experience which it has gained in carrying out the inspections.

Lightning.—On Wednesday last week a severe thunderstorm broke over Glasgow, about three in the afternoon. The lightning caused some damage in Cathcart, a southern suburb of Glasgow. The Fire Brigade was summoned to Cathcart Public School, where the lightning, by means of an iron pipe communicating with the roof, is stated to have set fire to the furnace-room and melted the pipes. About the same time a one-story building was also struck. A great part of one of the gables was completely demolished, and the upper portion of the chimney was sent through the roof. The zinc piends in connection with the roofing, as well as the rhones, were torn and twisted, and a great number of slates were stripped off. The gas piping was ripped away from the wall, and a sewing machine which had been standing in a corner was thrown into the middle of the kitchen. On Thursday last week the North of England was visited by a severe storm. At Chorlton-cum-Hardy a labourer was killed, and houses were struck by lightning at Rotherham and Masbro'.

Electric Street Railway Litigation in the United States.—The Supreme Court of Michigan recently gave judgment in the case of the Detroit City Railway Company *v.* Mills. The appellants were property owners on an avenue on which an electric road was built, and abetted a movement to cut down the Company's poles, on the ground that the Company were trespassers. The Company secured an injunction, which was made perpetual by the Supreme Court. The judges were of the opinion that the use of streets for street railway purposes does not impose such new burdens, that it is beyond the power of the city to authorise their construction without compensation to adjoining property owners. The Court held, however, that the tracks cannot be constructed in a street too narrow to admit the passage of cars and other vehicles at the same time, that the road-bed and track must be built substantially with the level of the street, so as to permit vehicles to cross without difficulty, and that the poles must be placed so as not to interfere with the right of ingress and egress to abutting property.

Pelton Water Wheels.—Mr. Ross E. Browne, of the University of California, has, according to the *Engineering Record*, published some interesting figures derived from tests of Pelton water wheels made at the University. According to these tests, a wheel 15in. in diameter and 1·5in. wide, working under a 50ft. head, the nozzle being $\frac{7}{16}$in. in diameter, showed an efficiency of 82·6 per cent. When the nozzle was $\frac{3}{8}$in. in diameter, the efficiency was 82·5 per cent. On reducing the head to 8ft. the efficiency was 73 per cent. To obtain a high efficiency with these wheels, Mr. Browne states that the bucket surface at entrance should be approximately parallel to the relative course of the jet, and the bucket should be curved in such a manner as to avoid a sharp angular deflection of the stream. The number of buckets should be small, and the path of the jet in the bucket short to keep down the frictional resistance. The discharge end of the bucket should be as nearly tangential to the wheel periphery as is compatible with the clearance of the bucket. The speed of the buckets should be half that of the jet.

The Sargent Electric Steam Engine Indicator.—In the case of triple expansion engines with indicators placed on the ends of each cylinder it is desirable, in order to obtain accuracy, to indicate the several cylinders at exactly the same instant. With these facts in mind, says the *Electrical Engineer*, of New York, Mr. Frederick Sargent, the well-known electrical engineer of Chicago, has provided a means whereby the recording devices of several indicators can be operated from a distance at the same instant by one person, and the time of contact at each indicator be made of exactly the same duration. The coils of three electro-magnets are placed in series in the circuit of a battery. The armatures of these electro-magnets are fixed upon the movable sleeves of the indicator cylinders, by turning which the pencils are brought into contact with the paper on the drums. The armatures are normally held away from the end of the magnets, and hence, also, the pencils from the drums. When the circuit is closed, however, the sleeves are drawn around, the pencils are pressed against the paper on the drums, and the cards taken.

Electricity and Gas in Factories.—The following quotation from the last report of the Chief Inspector of Factories tells its own story :—"The introduction of the electric light into factories will conduce very much to the healthiness of some occupations, and the comfort of all. Mr. Beaumont, H.M. Inspector for Bradford, has procured the following comparison of the temperature in a wool-combing shed when lighted by electricity and by gas light during 24 hours :—

Time.	Electricity. Deg.	Gas. Deg.	Time.	Electricity. Deg.	Gas. Deg.
7 p.m.	93	95	1 a.m.	96	108
8 p.m.	94	101	2 a.m.	95	108
9 p.m.	94	104	3 a.m.	95	107
10 p.m.	95	106	4 a.m.	95	107
11 p.m.	96	108	5 a.m.	95	107
12 p.m.	96	109	6 a.m.	95	107
Average	95 deg. electricity			105·1 deg. gas	

Wool-combing requires that the machine should be heated, and, as the operations continue frequently night and day, it will be readily conceived what the condition of the atmosphere must be when heated by the machinery and gas."

Platinum in Incandescent Lamps.—The scarcity of platinum has forced lamp manufacturers, says the *Electrical Engineer*, of New York, to exercise the greatest economy in the use of it. In former days two stoutish pieces of platinum were employed, the ends of which extended some distance both inside and outside the sealed portion. To reduce this as much as possible the following method was employed. This consisted in first soldering a comparatively fine short platinum wire to a copper wire, and sealing it in such a manner that the platinum wires extended but a small distance into the seal. The latest method adopted has, however, brought down the amount of platinum required to a still smaller quantity. A short piece of platinum wire is joined to two copper wires, one of which passes into the lamp bulb and the other out to the socket terminal. The glass is sealed around this platinum wire, and for a short distance beyond, covering a small portion of the copper wire. This forms a perfect seal, and, at the same time, reduces not only the length of platinum wire required to $\frac{1}{8}$th of an inch, but, in consequence, also allows of considerable reduction in its cross section.

Electrical Safety Apparatus for Miners' Cages.—At the general meeting of the Federated Institution of Mining Engineers, on Friday, May 29th, Mr. John Yates read a Paper on "An Electrical Safety Apparatus for Cages." He said that, although great advances had been made in recent years in nearly every branch of mine engineering, we were no better off to-day for a reliable safety cage than we were 20 years ago. According to the reports of Her Majesty's Inspectors of Mines there were, between the years 1880-1890, no less than 45 fatal accidents, resulting in 87 deaths, caused by the breaking of ropes and chains in shafts. Experience had shown that an apparatus which acted indirectly through the medium of a spring or otherwise was not to be relied upon. For some time past he had been at work on the matter, and the result of his labours had been the invention of an apparatus which appeared to promise safety in case of breakage of rope. The principle of his invention was to use the hauling rope as the means for conveying a current of electricity to four electro-magnets with the cage, each of the magnets sustaining a gripping cam. On the fracture of the rope and the breaking of the current, the cams would drop into play against the guides.

Repairing Incandescent Lamps.—How to turn broken filament lamps to good account has long been an object with lamp makers and others. According to M. A. Hess, in *La Lumière Electrique*, a good commercial method of renewing used-up incandescent lamps has been devised by M. Pauthonier. A hole is cut in the top of the glass bulb, the broken filament is taken out, and the carbon deposited on the interior of the glass is removed. A new filament is then introduced, and the bulb is filled with a liquid hydro-carbon. The ends of the new

Digitized by Google

filament are pressed against the stumps of the old one by pliers, the arms of which, insulated from each other, serve as conductors for the current, which, passing from one arm to the other at the juncture of the carbons, decomposes the hydro-carbon, and gives rise to a dense deposit, which firmly seals the ends together. The resistance of the new filament is not affected by being placed in the hydro-carbon, since it is not traversed by the current. The renewed lamp is then dried, exhausted, and sealed in the ordinary manner. The saving effected is said to amount to 75 per cent., being the difference between 1fr. 40 centimes, and 35 centimes.

Taunton, West of England, and South Wales Electrical Engineering Exhibition.—An Electrical Engineering Exhibition will be opened, in Taunton, on August 1st, closing on October 31st, on the grounds adjoining the Taunton Electric Lighting Company's central station in St. James'-street. The Exhibition will be opened daily from 2 p.m. to 10 p.m. Taunton being the centre of the West of England and South Wales district, situated on the main line of the Great Western Railway, and the junction of four branch lines of railway, it is anticipated that there will be a large attendance. It is proposed to run an electric omnibus between the Exhibition and the railway station during the time the Exhibition is open, and to place one or two electric launches on the river Tone. Exhibitors must run their own wiring over the space allotted to them. Electrical energy will be provided at 4½d. per Board of Trade unit. The charge for space will be 2s. 6d. per square foot. All exhibits must be in order by July 27th. Applications for space must be made on the printed forms, to be obtained from the Manager and Secretary, Bath Electric Light Works, Bath, which must be filled up and returned on or before the 30th inst.

The Underground Main Question.—To every question there are at least two sides, says *Modern Light and Heat*, one of which is bright, the other gloomy. So long as the former is visible, all is apparently well; but when the other side comes into view it is not so pleasant. The bright side of the municipal lighting and underground wire question has evidently been so long dazzling that many of our municipal bodies have been unable to look at it from but one standpoint, and have acted accordingly. In some cases the best results have not been attained. For instance, some time ago, the city of Indianapolis thought it was the proper thing to compel electric light wires to be placed underground, and they were so placed. A private corporation was doing the lighting, so that the city had to go to no expense. Now the dark side of the question looms up because the city fathers think that there ought to be more and cheaper lights; but the fact that an ordinance has been passed, forbidding the use of overhead wires for arc and incandescent lighting, prevents the accomplishment of this result, unless the ordinance be repealed. Underground conduits for electric wires are by no means such inexpensive luxuries as people are wont to imagine; and certainly, unless a company were assured a long franchise and a large business, it could not afford to come into a city where it was necessary to place the wires underground.

Wheatstone's Determination of the Velocity of Electricity.—In the Paper on the Motion of Electricity in Wires, Kirchhoff, in 1857, first showed that under certain conditions electricity moves in a thin wire according to the laws of wave-motion, and with a velocity equal to that of light. The agreement between the velocities of electricity and of light only holds, however, when electricity travels in a straight wire stretched in the air. If we apply the bases of his calculation to other cases, for instance, a wire which is bent backwards and forwards in zigzag or is wound in a spiral, it is found that electricity travels under these conditions with a far greater velocity. In Wheatstone's well-known method 20 plane windings of drawn-out wire were used, and the velocity of electricity was found by this measurement to be half as much again as that of light. In the preceding, says Prof. J. Stefan, in a recent number of the *Wiener Berichte*, I think I have given the correct explanation of this result. I have, however, also attempted to give this explanation an experimental basis, and for this purpose I have employed the method given by Hertz of producing stationary electrical waves in wires. I have used a similar conductor to that of Wheatstone, but on a smaller scale, and connected it with a couple of long straight wires, and compared the length of a wave in the conductor with the length of the same wave in the straight wires. The wave in the conductor is considerably longer, and in accordance with this the velocity of electricity in the conductors is greater than in the straight wires, and, according to my experiments, in a ratio which even exceeds that found by Wheatstone.

Dynamo Telegraph Plant at St. Louis.—In the Western Union Company's new central office at St. Louis the current is entirely supplied by dynamos. The engine and dynamo room is 36 by 47ft., and contains three 15 H.P. Rice engines. Each engine is belted to a separate shaft, to which is belted a group of five or seven telegraph dynamos. The shafting is supported entirely independently of the building, to prevent noise or vibration being communicated to it. The 19 telegraph dynamos are supplied by the C. and C. Electric Motor Company, and are arranged in two groups of seven and one group of five. The two groups of seven are each divided into sections for supplying main line, local, and loop circuits. Five dynamos of each group are connected in series and supply the main lines, the sixth dynamo supplies the loop circuits, and the seventh supplies the local circuits. The third group of five dynamos is a reserve main line set, all five being connected in series. The dynamos are wound for a potential of 80 volts, but ordinarily will be run at 70 volts. A set will, therefore, give the following potentials: 70, 140, 210, 280, and 350 volts. The loop dynamos are wound for 30 volts, but will be run at 25 volts. The local circuit dynamos are wound for 10 volts, and will be run at 6 volts. The current capacity of the dynamos is as follows: Main line dynamos, 20 amperes; loop dynamos, 50 amperes; and local dynamos, 150 amperes. The fields of the series dynamos of each set are excited by the seventh dynamo, each field having a regulating resistance in circuit with it, giving independent regulation for each dynamo. Regulation can also be effected by changing the potential of the exciting dynamo.

City and Guilds of London Institute.—The following facts and figures connected with this Institute taken from the last report of the Council may be of interest. Both at the Central Institution, and at Finsbury College, the electrical department proves by far the most attractive, but the Council are of opinion that "although the success of this department cannot but be a source of satisfaction, it has been to some extent at the expense of the Chemical Department." The total number of students attending all four departments at the Central Institution during 1888–89 was 82, and 107 during 1889-90; for the winter term 1890-91, the figure is 140, and, including the regular students not attending all four departments, the total is 156. The amount voted by the Council for the Central Institution at the beginning of last year was £8,180, and the students' fees amounted in round numbers to £3,778, making a total of £11,952; the gross expenditure was £10,673, the *net* cost, after deducting the amount of students fees and other items, comes out at £6,677, which, taking the average number of regular students during 1890 at 140, amounts to £47. 14s. per regular student. At Finsbury Technical College during the last session the day classes were attended by 180 students, of which 95, or nearly 53 per cent., belonged to the electrical department. At present there are in all 184 day students, of which no less than 99, or 53·8 per cent., attend the electrical department. Some 1,164 evening class tickets were sold to 972 students; the number of tickets taken by apprentices under 20 years of age was 259, or about 22 per cent. of the total issue. The amount voted by the Council for the maintenance of Finsbury College during 1890 was £5,877, students' fees amounted to £2,820, making a total of £8,697. The gross expenditure has been £8,564, and the net expenditure £5,582, deducting from this sum the £275 for electric light extension, and taking the average number of day students during 1890 at 182, the net cost per day student comes out at £29. A sub-committee appointed in July, 1889, with reference to the completion of the equipment of the Central Institution recommend an expenditure of £5,100 for this purpose. The total sum expended by the City Companies upon the City and Guilds of London Institute since its foundation in 1878 amounts to £352.543.

MAGNETISM IN IRON AND OTHER METALS.*—XLI.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 8.*)

§ 143. Strain caused by Magnetisation.—Closely associated with the changes of magnetisation that are caused by strain are the changes of form which a piece of iron, or other magnetic metal, is observed to undergo when it is magnetised, or when its magnetism is changed. The fact that strain alters magnetism involves this converse, that change of magnetism is accompanied by strain.† The earliest experiments on the subject were those of Joule,‡ who found that the length of a soft iron rod was increased by the application of magnetising force, within the limits of force to which his experiments extended. The extension was accompanied by lateral contraction, with the result that the volume of the rod did not sensibly change. To show this, the experiment was made of magnetising the rod within a tube full of liquid, which was closed, except for an extended portion with a narrow bore, the rise or fall of the liquid in which would have indicated any change of volume on the part of the iron. Later experiments on the extension of rods were made by Mayer,§ who dealt specially with steel; and by Barrett,‖ who extended the inquiry to nickel and cobalt, finding that nickel retracted when magnetised. It is unnecessary for our purpose to refer to these early experiments in detail, for in recent years the matter has been exhaustively examined by Shelford Bidwell, whose results have

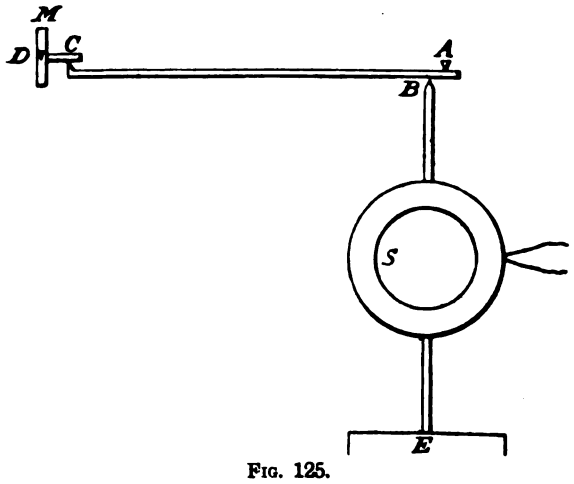

FIG. 125.

harmonised much that was apparently contradictory in the statements of previous investigators. Dealing with rings as well as rods (to secure uniform magnetisation and determinate magnetising forces), Bidwell has tested iron, steel, nickel, and cobalt throughout a very wide range of magnetising force, and has found that when the force is pushed to high value the character of the action becomes greatly changed. He has also examined the modifying influence of externally imposed tensile stress on the change of length caused by magnetisation. The following is a brief summary of the more important of his results¶:—

The method of experiment is shown diagrammatically in Fig. 125, where S is the ring to be tested. The change of length along the lines of magnetisation was deduced by observing the change in the diameter of the ring which occurred when the magnetising current was applied. The ring S was placed between a fixed support E, and a long lever B, pivoted on a fixed fulcrum at A. The long end of the lever at C tilted a small mirror M hinged on a fixed support by a knife edge at D. The deflection of the mirror was read by means of a distant scale, the sensibility of the arrangement being such that readings could be taken corresponding to about one ten-millionth of the length of the specimen. The ring was jacketed with wood to exclude, as far as possible, the heating effect of the magnetising coil, and with the same object the circuit was never allowed to remain closed for more than a fraction of a second. A similar arrangement was used for tests of rods. The ring or rod was first demagnetised by reversals, then a current of known strength was passed for a moment through the magnetising coil and the deflection was noted, the dead-beat character of the apparatus allowing this to be done almost instantaneously. Then the specimen was again demagnetised and another current was

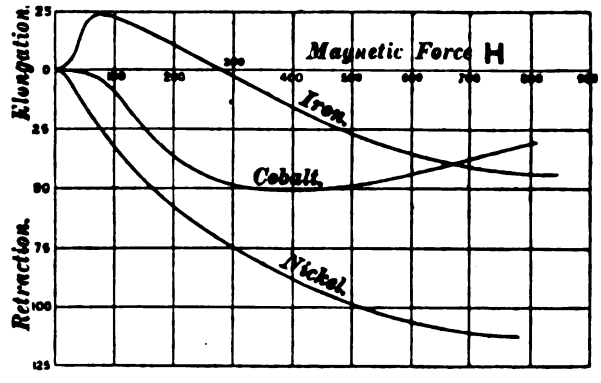

FIG. 126.—Elongation and Retraction of Iron, Nickel, and Cobalt through Magnetisation (Bidwell). The elongations and retractions are stated in ten-millionths of the length.

applied, and so on. In some of the experiments magnetising forces approaching 1,500 C.-G.-S. units were employed.*

Beginning with small magnetising forces, Bidwell found his iron rods and rings elongate when magnetised, by amounts which appear to increase at first in something like simple proportion to the degree of magnetisation. But as the magnetising force increases, the elongation of iron passes a maximum, becomes reduced, and vanishes when the magnetising force is about 300 C.-G.-S. With higher forces still, the iron retracts instead of elongating when the magnetising force is applied, and this retraction appears to tend to a finite limit as the force is further increased. The maximum amount of elongation, which is observed in comparatively moderate fields (say about 100 C.-G.-S.), varies in different specimens; it ranged in Bidwell's experiments from about $\frac{1}{200,000}$ to $\frac{1}{400,000}$ of the length. The amount of retraction under very strong force may be as much as $\frac{1}{130,000}$

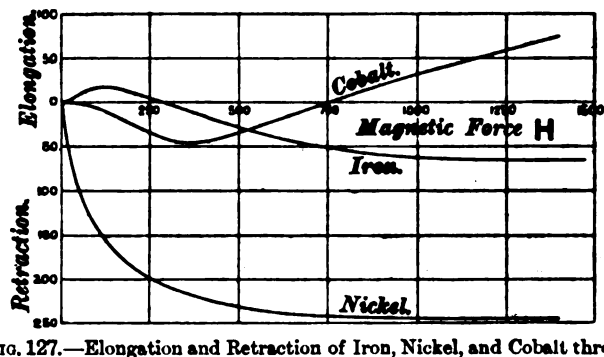

FIG. 127.—Elongation and Retraction of Iron, Nickel, and Cobalt through strong Magnetisation (Bidwell). The elongations and retractions are stated in ten-millionths of the length.

of the length. These figures refer to iron. Steel behaves in much the same way, but suffers less elongation than iron under moderate forces.

In nickel, on the other hand, there is retraction from the first, and the amount apparently tends to a fixed limit as the magnetising force is raised to high values.

In cobalt the action is less simple. Weak magnetising forces cause sensibly no change of length. Stronger forces cause retraction, but the amount of that passes a maximum, and

vanishes with further increase of the force, after which, with stronger force still, there is *extension*, the amount of which was still increasing fast in the strongest field to which the experiments were carried. These results are well shown by Figs. 126 and 127, taken from Bidwell's principal paper. In Fig. 126 the magnetic force ranges up to 800 units. In Fig. 127 it is carried to nearly twice that value. The specimens of metal tested were different in the two cases. The general results, however, agree well. The nickel used in the experiment of Fig. 126 shows more retraction than the other. The amount of retraction under the strongest magnetic force is about $\frac{1}{10,000}$ of the original length.

§ 144. **Modification of the Results by applying Tensile Stress.**—In a later Paper, Bidwell has described experiments made with rods of iron, nickel, and cobalt, in which the change of length caused by magnetisation was made to take place while a load was hanging from the specimen. The results for iron are shown in Fig. 128, the numbers attached to the curves being the values of the externally applied stress in kilogrammes per square cm. The effect of tension in iron is to lower the curve, reducing the maximum extension which magnetisation causes, and finally making it vanish. Under the greatest loads used in these experiments, the iron retracted from the first as the magnetising force was increased.

In nickel the effect of tensile stress is to raise the curve in its earlier stages, making the amount of retraction caused by magnetisation less if the test is made while there is pull, than if it is made while there is no pull. This applies to magnetising forces of moderate strength. But in stronger fields the

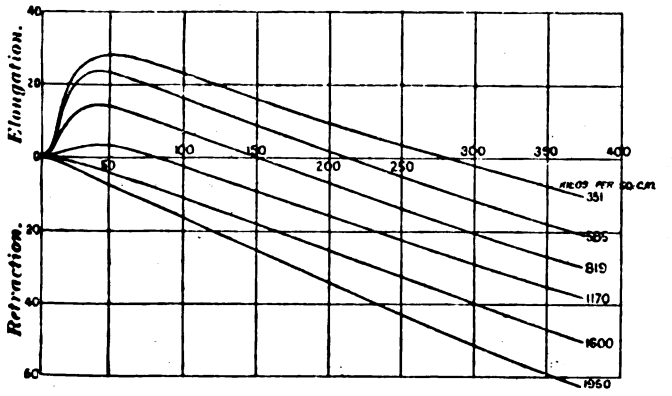

Fig. 128.—Changes of Length caused by Magnetising Iron under various amounts of longitudinal pull (Bidwell). The elongations and retractions are stated in ten-millionths of the length.

magnetic contraction is increased by the presence of small amounts of pull, and decreased by the presence of large amounts of pull.

In cobalt, the changes of length which the metal undergoes in being magnetised were found to be almost, if not quite, independent of the presence of pulling stress. Cobalt stands in striking contrast in this respect to iron and nickel, in both of which the modifying influence of pull is conspicuous.

§ 145. **Internal Stress in a Magnetised Rod or Ring, due to the Magnetisation.**—Some part of the retraction which is observed in experiments such as these is to be ascribed to the state of internal stress into which the metal is thrown by its magnetisation. Imagine a cross-section to be taken through the substance of a ring or very long rod, the intensity of magnetism in which is I. The surfaces which are opposed to each other at the imaginary plane of section act as a pair of plates of attracting matter, the surface density of which is I. The force which either exerts on unit quantity of the other is (by a well-known proposition in the theory of attraction) $2\pi I$. But there are I units of attracting matter per unit of area of the plate, hence the whole force exerted by one plate on the other is $2\pi I^2$. This is the stress between the two, existing in virtue of the magnetisation, and the same stress exists at every imaginary surface of section. In other words, there is an internal stress which tends to contract the length of the piece, the intensity of which is $2\pi I^2$ in dynes. To find the amount of the contraction per unit of length which this internal stress will cause, we have only to divide the intensity of this stress by Young's modulus for the material, also expressed in dynes. Young's modulus for iron is about $1{\cdot}8 \times 10^{12}$ dynes. To see what is the greatest amount of contraction which can in any case be attributed to the cause referred to here, we may take for I its limiting value in iron, namely, 1,700 (see § 98), and the result is $\frac{2\pi \times 1{,}700^2}{1{\cdot}8 \times 10^{12}}$ or $\frac{1}{1,000,000}$ very nearly. In the experiments which have been described, I did not, of course, reach so high a value as 1,700. It is clear, then, that the effect in question is at least of the same order of magnitude as the contraction which actually occurs in iron. Bidwell, who has discussed the matter from the same point of view, has, however, come to the conclusion that the internal stress due to magnetisation is by no means the sole cause of the retraction which iron undergoes when it is strongly magnetised. Comparing the values of the retraction at two points in his curve, just when retraction has begun to take the place of extension with the values of the internal stress as measured by the force required to separate two portions of a divided bar magnet, he contends that the difference in the amount of internal stress accounts for only about one-fifth of the actual change of length.*

ON ALTERNATE CURRENT THEORY.

BY W. E. SUMPNER, D.SC.

The sine function has been much abused by writers dealing with alternate current theories, but several cases could be pointed out in which those who have been very free in expressing dissatisfaction with it have afterwards felt forced to use it extensively. It is, no doubt, true that alternating currents sometimes vary in a manner very different from an ordinary sine law, but this is no real reason why the sine function should not be used for purposes of calculation; and, in the writer's opinion, most of the errors to which its use has led have been due, not to any inability of the sine function to truly represent the essential facts of the case, but rather to the circumstance that the meaning of the quantities involved in the equations have been frequently misunderstood. The simplest periodic function is the sine, and any attempt to replace it must lead to greater complication; while graphical or geometrical methods are either too slow, or require too much care in drawing, to be of much service, however admirable they may be for clearly representing the nature of the reactions going on. Our endeavour should, therefore, be to find out how to use the sine function so as to introduce no error into our calculations when the current and potential variations do not follow a strict sine law, and it is in the hope of aiding in this search, and with the view of pointing out some mistakes which are often unconsciously made, that the present article is written.

In dealing with electricity from an engineering point of view, there are three quantities, all of equal importance, which have to be considered. These are voltage, current, and electrical power. The two former determine the condition of supply, while the latter denotes the output. When the currents are steady a very simple relation connects them, for if W is the output in watts of a current, A amperes at voltage V, we have $W = V A$. This equation is, however, not necessarily true of varying currents, and, in fact, it is meaningless till the values of V and A are defined. The definitions adopted depend on the heating caused by the passage of electrical currents; a varying or alternating current being said to be equal to that steady current which would produce the same amount of heating in a non-inductive resistance, and a similar definition being employed for potentials. As the rate at which heat is generated in a non-inductive wire of constant resistance is propor-

* Bidwell; *Phil. Trans.*, 1888, pp. 217-218.

Digitized by Google

tional to the square of the current, or voltage, applied, these definitions are accurately represented by the equations,

$$\left.\begin{aligned} A^2 &= \frac{1}{T}\int_0^T A_t^2\,dt \\ V^2 &= \frac{1}{T}\int_0^T V_t^2\,dt \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (1),$$

in which A_t is the instantaneous value of the current at the time t, A is the nominal value of the current as read by an alternating current ammeter, and

$$R\,A^2\,T = \int_0^T R\,A_t^2\,dt \quad . \quad . \quad . \quad . \quad . \quad (2)$$

is the heat generated by the passage of this current through a wire of resistance, R, during a time, T. Similarly we have $A_t = \frac{V_t}{R}$, and $A = \frac{V}{R}$, if the wire is non-inductive, and, accordingly, the last equation may be written

$$\frac{V^2}{R}\,T = \int_0^T \frac{V_t^2}{R}\,dt \quad . \quad . \quad . \quad . \quad . \quad (3).$$

If W_t is the instantaneous value of the rate at which energy is being transferred,

$$W_t = V_t\,A_t,$$

and W, or the average power in watts, is such that

$$T\,W = \int_0^T V_t\,A_t\,dt; \text{ or } W = \frac{1}{T}\int_0^T V_t\,A_t\,dt \quad . \quad . \quad (4).$$

If the power is being supplied to a non-inductive resistance, R, we have $V_t = A_t\,R$ and $W = V\,A$, just as if the currents were steady, but in general this will not be the case, and we shall have

$$W = V\,A\,\eta \quad . \quad . \quad . \quad . \quad . \quad . \quad (5);$$

where η is some numerical factor, whose value depends on the way in which the currents and potentials vary. The value of the quantity η is of the greatest importance, and it is easy to show that it can never be larger than unity, although it is equal to one when the resistances are non-inductive. In proving this, it is not necessary to assume that the currents vary according to a sine law; all that we need suppose is that the values of V_t and A_t vary in the same sort of way, and then it is evident that the value of the integral (4) must be greatest when the maximum values of V_t and A_t occur simultaneously. If, however, this is the case, V_t and A_t are approximately proportional to each other at every instant, and under these circumstances we shall have

$$W = V\,A,$$

or $\eta = 1$. The maximum value of η is therefore unity, and this fact we may very conveniently express by the equation

$$\eta = \cos\theta \text{ or } W = VA\cos\theta \quad . \quad . \quad . \quad . \quad (6),$$

where we may define θ to be the *difference of phase*, or lag, between the volt and ampere curves. The angle θ has a very definite meaning when the current variations can be assumed to follow a sine law, since it is directly proportional to the time elapsing between the moments at which the current and potential attain their maximum values. For this reason it is preferable to consider η in equations (5) and (6) as being the cosine of an angle rather than as a proper fraction, but in doing so it is well to notice that no assumption has been made regarding the way in which the currents change. In practice, θ is small, and cos θ is very nearly unity, except for highly inductive resistances. For the primary coils of small transformers, whose secondary coils are open circuited, θ lies between 30 and 50 degrees, and cos θ varies from ·9 to ·6. For large unloaded transformers, for well-made choking coils, and for condensers absorbing very little energy in heat, the angle θ may be as much as 80° (cos 80° = 0·17), and in very exceptional cases 85° (cos 85° = 0·087), so that the quantity η may vary from 0·1 to 1, although when large amounts of power are being transmitted, cases in which η is as small as 0·9 are rare.

A conductor through which a steady current A is flowing requires to be subjected to a voltage $V = R\,A$, where R is the resistance of the conductor as determined by the Wheatstone Bridge. The value of R is of course constant, so that if A is doubled V is also doubled. With alternate currents this equation between V and A no longer holds, but we have

$$V = I\,A \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7),$$

where I is called the impedance of the conductor, and is a quantity whose value may be stated in ohms just like an ordinary resistance. In nearly all cases, too, the value of I is the same whatever the value of A, provided the current frequency remains the same, although this is not strictly true when the conductor surrounds, or is in the neighbourhood of, masses of iron. With alternate currents of ordinary frequencies I may very much exceed R. In all cases the product $A^2\,R$ measures the rate at which energy is used up in the conductor as heat; but whereas this product denotes the whole power absorbed by the conductor when A is a steady current, the power supplied by an alternating current to the same conductor may far exceed this quantity, owing to inductive effects in neighbouring circuits and other causes. Suppose X is the number of ohms that has to be multiplied by the square of the current to obtain W, the watts absorbed by the conductor, then

$$W = A^2\,X \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8),$$

but by (6) and (7),

$$W = V\,A,\ \cos\theta = A^2\,I\cos\theta,$$

or

$$X = I\cos\theta \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (9);$$

and if we define a new quantity Y by the equation

$$Y = I\sin\theta \quad . \quad . \quad . \quad . \quad . \quad . \quad (10),$$

we shall have

$$I^2 = X^2 + Y^2$$

$$\tan\theta = \frac{Y}{X},\ \sin\theta = \frac{Y}{I},\ \cos\theta = \frac{X}{I} \quad . \quad (11).$$

There are thus four distinct resistances, or rather ohmages, to be considered in connection with any conductor subjected to alternate currents. These we have distinguished by the letters R, I, X, and Y. The two former have well-known names, but the two latter are not recognised. The first of these quantities, R, is the resistance of the metallic conductor, and is the most definite and constant of them all, but it is also usually the one of least importance. The impedance I, as we have said, is approximately a constant for a given frequency of the current, but the values of X and Y may vary considerably as the current changes, even although the frequency remains the same. In much that has been written about alternate currents the quantities R and X have been frequently confused together, although it is well known that the power absorbed by a conductor may, with alternating currents, greatly exceed that lost in heating the wires through which the primary current passes. The value of Y, too, has been frequently estimated far too high, in consequence of the fact that X has been estimated too low.

It seems, therefore, desirable to point out the meaning of these quantities in certain simple cases, and to show, by actual reference to figures, the character of the variations to which their values are subject.

Hitherto we have made no assumption about the way in which the current changes occur, and in what follows the results given will be equally true whether the currents are sinuous or otherwise; but we shall now find it convenient, for the sake of definiteness, to assume that the currents and potentials vary according to a simple sine law. Moreover, as the considerations we have alluded to were very fully discussed in a rather lengthy Paper, entitled "Interference with Alternating Currents," by Prof. Ayrton and the present writer, and which, although read before the Physical Society in March last, has not yet been printed, it may be of interest to publish here the following short extract bearing on these questions:—

"Suppose $A_t = A_0$, $\sin p\,t$ is the value of the current flowing at any instant in a coil of wire whose resistance is R and whose self-induction is L. The potential V_t at the ends of the coil will be

$$V_t = R\,A_t + L\frac{d\,A_t}{d\,t} \quad . \quad . \quad . \quad . \quad . \quad (12),$$

$$= R\,A_0\sin p\,t + L\,p\,A_0\cos p\,t,$$

$$= \sqrt{R^2 + L^2\,p^2}\ A_0\sin(p\,t + \theta),$$

Digitized by Google

where $$\tan\theta = \frac{Lp}{R} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (13);$$

and if V and A are the values of the voltage and current, as read by alternate current instruments,

$$V = IA \qquad \text{where } I^2 = \sqrt{R^2 + L^2 p^2} \quad . \quad . \quad (14);$$

moreover, if W is the power in watts absorbed by the conductor, that is the mean value of the product $V_t A_t$,

$$W = \frac{1}{T}\int_0^T V_t A_t \, dt \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (15),$$

$$= \frac{1}{T}\int_0^T [R A_0^2 \sin^2 pt + Lp A_0^2 \sin pt \cos pt] \, dt$$

$$= R A^2.$$

The value of L is assumed constant, so that the second term vanishes in the integral, which is taken over the period τ of the alternating current. This case is, however, the simplest which can arise, and all the inductive conductors occurring in practice possess iron cores which absorb power in hysteresis or eddy currents, or transfer energy to secondary coils. Considering first the case of a transformer whose core gives rise to no dissipation of energy, equation (12), suitably modified, may be written

$$V_t = R A_t + L\frac{dA_t}{dt} + M\frac{dB_t}{dt} \quad . \quad . \quad . \quad (16),$$

where M is the mutual induction between the coils, and B_t is the current flowing through the secondary. When this value of V_t is substituted in equation (15) the value of W is found to exceed RA^2 by the power transferred to the second coil. The values of L and M are known to vary with the value of A, the current in the primary coil, but may be assumed to be constant throughout the period. In order, however, to account for the fact that the core itself absorbs heat owing to hysteresis and eddy currents, it becomes necessary to assume that these coefficients vary during the period; and, under these circumstances, it may well be questioned whether the method of analysis by means of these coefficients, as exemplified in equation (16), and so frequently resorted to by writers on alternate currents, is either useful or correct. It is far preferable to write equation (16) as follows:—

$$V_t = R A_t + \frac{dN}{dt} \quad . \quad . \quad . \quad . \quad . \quad (17),$$

where $\frac{dN}{dt}$ is the induced electromotive force generated by the lines of force cutting the primary coil. Since each of the quantities V_t and A_t is assumed to be a sine function, $\frac{dN}{dt}$ must be so likewise, and its value, like that of V_t in equation (12), may be expressed as the sum of two rectangular components

$$\frac{dN}{dt} = X_n A_0 \sin pt + Y_n A_0 \cos pt \quad . \quad . \quad (18),$$

of which the first, $X_n A_0 \sin pt$, is in phase with the current $A_t = A_0 \sin pt$, while the second differs in phase from it by a quarter of a period.

Equations (17) and (18) combine to the following:

$$V_t = (R + X_n) A_0 \sin pt + Y_n A_0 \cos pt,$$

and, comparing this with equations (12) and (15), we notice that $R + X_n$ takes the place of R, and Y_n replaces Lp. The power absorbed is measured by $R + X_n$, and the former of these quantities denotes the power wasted in heating the primary coil, and the latter the power transferred to the core, or secondary circuit. In general, whatever the nature of the conductor may be, if $A_t = A_0 \sin pt$ and $V_t = V_0 \sin(pt + \theta)$, the quantities which replace R, and Lp in (12) are X and Y, where

$$X = \frac{V_0}{A}\cos\theta \qquad Y = \frac{V_0}{A}\sin\theta,$$

and $$X^2 + Y^2 = \frac{V_0^2}{A^2} = I^2.$$

The use of the quantities X and Y seems preferable to that of coefficients of induction, for several reasons. They are just as easily found experimentally, and have a more tangible meaning. Indeed, the values of X and Y have always to be found before the values of the coefficients usually employed can be determined. Their values are expressed in ohms just like resistances. X is directly associated with the power which is being withdrawn from the source, and Y represents the power which corresponds with the magnetic changes going on, but which is not permanently absorbed. Although X and Y vary as the currents change, yet they do not vary more than the coefficients themselves.

The way in which these quantities vary in the case of a transformer is best indicated by reference to a few actual measurements. When the secondary circuit of a particular transformer was open, the primary coil was found to take a current of 0·86 amperes under a pressure of 60 volts. At the same time the power absorbed was found, by a voltmeter method we have devised, to be 43·3 watts.

Hence $$X = \frac{43{\cdot}3}{{\cdot}86 \times {\cdot}86} = 59 \text{ ohms};$$

$$I = \frac{60}{{\cdot}86} = 70 \text{ ohms};$$

$$Y = \sqrt{I^2 - X^2} = 37{\cdot}6 \text{ ohms}.$$

The angle of lag between the volts and amperes, as calculated from the formula $\cos\theta = \frac{X}{I}$, comes out to be about 33°. The resistance R of the primary coil, as measured by the Wheatstone's Bridge, was only 0·08 ohms, so that X is more than 600 times as great as R, and if $\cos\theta$ had been calculated from the formula $\cos\theta = \frac{R}{I}$, which is incorrect, but frequently relied upon, the value of θ would have been estimated quite wrong. When the above transformer was working at full load, so that the primary current was 15 amperes, the angle of lag was quite inappreciable, and

$$Y = 0$$

$$X = I = \frac{60}{15} = 4 \text{ ohms}.$$

Each of the quantities X, Y, and I, diminishes as the load on the transformer increases. The value of I for a constant potential transformer is, of course, inversely proportional to the current in the primary circuit."

From some numbers recently published by Dr. Fleming in his Paper, just read before the Institution of Electrical Engineers, it is possible to point out a very remarkable example of the great differences in the values of the quantities we have represented by X and R, although these quantities seem to be regarded as identical by many who have written on alternate currents, since the fact that they differ has not been alluded to. According to Dr. Fleming, the resistance of the 10,000-volt coil of one of the 150 H.P. transformers in use at Deptford is 3·5 ohms, and when the low-pressure coil is delivering no current, the current in the primary is only 0·4 amperes. The value of X must, therefore, be such that $(0{\cdot}4)^2 X$ is equal to the power wasted in the core, estimated in watts. This waste is probably not less than 2 per cent. of the full load, but assuming that it is only 1 per cent., or 1·5 H.P., we have

$$X = \frac{1{\cdot}5 \times 746}{{\cdot}4 \times {\cdot}4} = 7{,}000 \text{ ohms},$$

$$I = \frac{10{,}000}{{\cdot}4} = 25{,}000 \text{ ohms},$$

$$Y = 24{,}000 \text{ ohms},$$

and the angle of lag θ, whose tangent is Y/I, is about 74 deg. The value of X is thus no less than 2,000 times the resistance (R = 3·5) of the primary winding, and even when the full load current is on the ratio is still extremely large.

THE FRANKFORT ELECTRICAL EXHIBITION.

(FROM OUR OWN CORRESPONDENT.)

Messrs. SCHUCKERT and Co. have within the last few days made great progress with their installation, and it will shortly be quite complete. Like Messrs. Siemens and Halske, this firm is erecting a central electric lighting station. The plant includes a dynamo, coupled direct to a two-cylinder condensing engine by Kuhn of 250 to 300 H.P., the initial pressure being about 120lb., and the engine running at 160 revolutions; and a 100 H.P. compound engine, coupled to a dynamo used for charging the accumulators belonging to the central station. There are also a 100 H.P. machine, by Woolf, of Nuremburg, driving two dynamos (direct and alternating) for the transmission of power, and a 30 H.P. Dävel engine, coupled direct to a dynamo supplying the search lights which have been installed in a tower in the Exhibition grounds. In the building devoted to matters connected with railways and tramways, Messrs. Schuckert and Co. show a model lighting truck. They have also undertaken the execution of the electric tramway, on the closed-conduit system, to the river Main, and are erecting a station in the Palm Gardens, from which the power will be transmitted to the Exhibition.

The COLOGNE ACCUMULATOR WORKS, of Hagen, have a complete central lighting station for 500 glow lamps, consisting of a 20 H.P. steam engine, a compound-wound dynamo (200 amperes × 65 volts) by Lahmeyer, a dynamo giving 200 amperes at 25 volts, and a 36 cell accumulator battery. They also exhibit a battery of 52 cells, used by the Helios Company, of Cologne, which have a capacity of 1,080 ampere hours.

POKORNY and WITTEKIND, of Frankfort, who occupy a position near the middle of the Machinery Hall, have at present two dynamos running. One of 60 H.P. is driven by a horizontal single-cylinder steam engine, ropes being in this case substituted for the driving strap; the second is a 40 H.P. dynamo, driven by a high-speed single-cylinder engine. Among other dynamos not yet in operation are two interior pole machines, each of about 16 kilowatts, and two direct-current dynamos for lighting and for transmission of power of 33 and 16 kilowatts respectively.

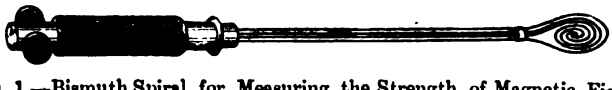

FIG. 1.—Bismuth Spiral for Measuring the Strength of Magnetic Fields. One-third actual size.

The exhibit of Messrs. HARTMANN and BRAUN is amongst the most forward. This firm has a large pavilion devoted solely to their use. Electrical measuring instruments are a speciality of Messrs. Hartmann and Braun, and they have numerous and important novelties in this department, of which only a few can be mentioned now. An instrument for measuring the intensity of a magnetic field is shown (Fig. 1), the principle of which rests on the alteration in resistance which a wire of bismuth undergoes when placed in a magnetic field. A thin insulated wire of this metal is wound bifilarly into a spiral, the ends being connected with the terminal screws of a vulcanite handle. The thickness of the spiral is only about 1mm. (·04in.), so that it can be inserted in very narrow spaces, as, for instance, the air-gaps of dynamos. The variation in the resistance is a measure of B, and 1,000 lines per square centimetre corresponds to a 5 per cent. variation; a more exact correspondence is to be seen from the gauge-curve of the instrument. Messrs. Hartmann and Braun have introduced a very practical improvement in the arrangement of the telescope and scale for mirror reading with the galvanometer. The telescope and scale are attached to an arm, which is movable, with a counterbalance round the instrument. By this means the instrument can be rapidly focussed and made ready for use; the telescope, as well as a small directing magnet, are removable at will. Amongst other new apparatus by this firm we may notice a Wheatstone bridge, for determining the resistance of conducting material in straight pieces, such as arc-lamp carbons, in which, by means of two consecutive observations, the contact resistance is eliminated. This instrument is adapted for small resistances, varying from 1 microhm to 5 ohms. Also a portable apparatus for the measurement of insulation, the instrument weighing about 30lb. This is a handy instrument, folding up into a small space, and capable of measuring resistances from 1,000 ohms to over 10 megohms. A second apparatus of this kind, with a battery, giving from 80 to 100 volts, and weighing about 44lb. altogether, measures up to 50 megohms. Two electricity meters are shown. The first consists of an ammeter (Fig. 2), in which the scale is exactly proportional to the current, the scale itself being usually left out; at fixed intervals the index of the ammeter is brought back to zero, and an ordinary registering apparatus is affected in proportion to the distance traversed by the index. This operation is done by an electro-magnet, which acts every minute in consequence of a contact made by a simple clock-work arrangement, and attracts an armature in connection with the axis of the pointer. The magnet acts for a few seconds, and is also used for the winding up of the clock-work, so that after the meter is set going no further attention is required. The coils of the electro-magnet have a high resistance, and take very little current. The meter is at present arranged for currents up to 50 amperes.

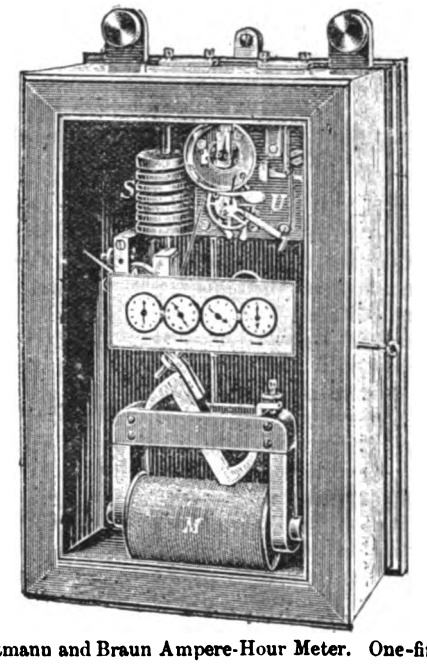

FIG. 2.—Hartmann and Braun Ampere-Hour Meter. One-fifth actual size.

The second instrument consists of a disc of copper, rotating between the poles of an electro-magnet, which is so arranged that the angular velocity of the disc is proportional to the strength of the current; the axis of the disc is attached to a registering apparatus, giving the ampere hours directly on the dials. This meter is made for currents from 50 to 1,000 amperes. Other new apparatus, of which detailed descriptions will be given later, include voltmeters giving signals by bells when the pressure is too high or too low; differential voltmeters, registering ammeters and voltmeters, and an electric pyrometer by Prof. Braun, reading directly up to 1,500° C.

In the Railway Apparatus Building the COMMITTEE OF THE PRUSSIAN STATE RAILWAYS exhibit their system of signals. The EASTERN TELEGRAPH COMPANY, in the Telegraphy and Telephony Hall, show Sir William Thomson's Siphon Recorder in its earliest and latest forms; Saunders' and Brown's self-acting Morse apparatus, requiring neither setting in motion nor winding up; relays and samples of cables. Messrs. Bullock and Brown's Unigraph is also on view. A loud-speaking telephone transmits music from Wiesbaden to the Hall, and the Munich and Frankfort operas can also be heard nightly, and the ubiquitous Phonograph forms one of the side-shows.

Later on electro-metallurgical processes will be exhibited in the Chemistry Hall, and a large proportion of the necessary apparatus is already *in situ*. Messrs. SIEMENS and HALSKE will undertake the electrolytic winning of copper directly from the ore and the production of ozone. This firm also supplies the electrical apparatus for the balloon (which has already made several ascents), such as a windlass driven electrically from the Machinery House in the Palm Gardens, a search light of 20,000 c.p. in the car, as well as telephonic apparatus.

Digitized by Google

The area at the command of the Exhibition has been found much too small, and so a large space has been taken on the banks of the Main, where SIEMENS BROS., of London, have a fine display of apparatus for ship lighting, torpedoes, &c. In fact, this section of the Exhibition may be termed the Marine or Naval Section, as it is here that the electric launches are to be found, and a charging station has been erected. Another feature of the Exhibition is the almost universal use of compressed paper tubes for the electric light wires and cables. These tubes are, of course, very light indeed, and have been approved by the insurance companies' representatives. It is needless to say that the hammered metal work for which Germany is famous is everywhere in evidence, and a very fine effect is the result. Some samples of this ware have already become familiar in England, through the agency of Messrs. BEREND AND Co., but here it is seen in endless variety.

It is only natural that one should expect to find this Exhibition similar to the many others of the kind, but the Directors have made a departure in the right direction. They have been at work for the past eighteen months, and have from the first given the various firms who have agreed to exhibit an official intimation of exactly what, out of the list of manufactures submitted by the firms, they were prepared to admit. This has resulted in making the exhibits of a most varied description. Many firms here, as in England, make almost everything, but have only been allowed to exhibit such examples of their manufactures as a committee of technical experts have first of all approved. This system of selection is worthy of imitation outside Germany.

The Exhibition is by no means complete, and it will be quite the middle of June before everything is in full working order. The financial success of the Exhibition is, however, we are informed, beyond doubt, as it has been calculated that 600,000 payments for admission will ensure financial equilibrium, and of this number 400,000 are already assured.

EXPERIMENTS WITH ALTERNATING CURRENTS OF HIGH FREQUENCY.*

For the purpose of his experiments, Mr. Tesla employed an alternating machine with 400 poles, which, when run at full speed, permitted him to obtain 20,000 alternations per second. The current was first run through a condenser in order to avoid the possibility of injury to the machine.

Alluding to the electro-magnetic theory of light, and to the Hertz experiments and those of Dr. Lodge, and their application to the production of an efficient source of light, Mr. Tesla considered the electro-magnetic waves as unavailable for the production of luminous effects, for the reason that long before we could reach the necessary frequency the conductor would become opaque to the passage of the waves. Not so, however, with the electrostatic waves or thrusts. These, no matter what their frequency, can excite luminous radiation. He reasoned that the static effects in the Hertz and Lodge experiments were excessively small, due to the fact that they were produced in a practically closed coil, the spark acting as a bridge, making the coil practically continuous and depressing the potential. To obtain the desired difference of potential we must work with an open circuit generator of high potential, and of high frequency, to enhance the electrostatic effects, and it was the recognition of this fact which led Mr. Tesla to the results he showed.

Mr. Tesla then started a spark coil in action, the primary of which was in connection with his alternator, which was speeded to give from 10,000 to 11,000 alternations per second. As the discharges took place between the terminals of the coil, an exhausted Geissler tube held in proximity to the discharge did not light; but, upon blowing out the arc, the tube lighted up.

Mr. Tesla then showed the influence of insulated bodies having considerable size upon the spark length demonstrating the effect of capacity upon the nature of the discharge. He showed this by wrapping an insulated wire of about one foot in length about one terminal of the coil, and touching the other terminal with a brass sphere held in the hand; under these conditions streams of light emanated from all sides of the wire. When the sphere was removed, however, the streams disappeared almost entirely. He then cut off the wire in successive lengths, and the stream discharges became more marked and brilliant. Another experiment consisted in attaching two spheres of about four inches diameter to the terminals. The spark passes first between the two points nearest to each other on the spheres, then works up toward their tops, is extinguished and is re-established at the first point, this being continuously repeated. The neighbouring exhausted tubes and lamps were illuminated and extinguished in unison with the action of the spark between the spheres. Mr. Tesla then showed these static effects in a non-striking vacuum. A tube of this natures when connected to the machine, glowed brightly, and the terminal, became incandescent. Mr. Tesla then remarked that if, instead of using a filament in a lamp—which necessarily limited us in the degree of incandescence which we could practically employ—we could use solid blocks of carbon, much higher efficiency could be obtained. Based upon this reasoning, he has constructed a lamp, which he showed, containing two blocks of carbon in non-striking vacuum. When connecting these two carbons to the two terminals of the coil, or one to one terminal and the other to a body of some size, the blocks can be raised to high incandescence. This Mr. Tesla followed by demonstration of the phenomena with an unexhausted globe, and a single filament mounted therein.

In order to still further verify the conclusions that the electrostatic effects are alone active, Mr. Tesla placed a Geissler tube at right angles to the coil and at its centre. In this position the tube did not light up. When placed at the ends, however, the tube lit up brilliantly and gave sufficient light to read by.

He then showed how exhausted tubes could be made to glow in an electrostatic field. For this purpose two large sheets of zinc were connected to the terminals of the machine at a distance of about 15ft. apart. The tube when placed between these sheets glowed brilliantly, and could be moved about freely.

Coming to the physiological effects, Mr. Tesla adjusted the conditions, so that by touching one terminal with a brass sphere he raised the potential of the coil so enormously that a stream of light came out on the other terminal, and he estimated the difference of potential to be nearly 250,000 volts, and then performed the remarkable experiment of receiving the total discharge in his body, protecting his hands from burning by the brass balls held in his hands.

The lecturer then came to another class of experiments. He stated that he had used a system of conversion from high tension to low with the enormous frequencies of the condenser discharges. Mr. Tesla then showed an interesting experiment which consisted in passing the converted currents, produced in the manner just described, through a copper bar $\frac{3}{8}$ in. in diameter and bent into a loop. Ordinarily such a bar would constitute a short circuit, but Mr. Tesla succeeded in bringing lamps stretched across the parallel sides of the bar to incandescence, demonstrating that the impedance in the loop connecting the two sides was so great as to practically prevent the current from passing through it and hence acting upon the lamps in the manner described.

We have given but the merest outline of the many beautiful and highly suggestive experiments made by Mr. Tesla. Notwithstanding the fact that Mr. Tesla excited the intensest interest of his audience for three hours, he was nevertheless unable, for lack of time, to bring before them many experiments of even a more striking nature.

* Abstract of a report which appeared in the *Electrical Engineer*, of New York, of May 27th, of a lecture given by Mr. Nikola Tesla, on Wednesday, May 20th, before the American Institute of Electrical Engineers, at Columbia College.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

FRIDAY, June 5th.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "The Implications of Science." By Sr. GEORGE J. MIVART, M.D., F.R.S.

SATURDAY, June 6th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "The Scientific Study of Decorative Colour." By Prof. A. H. CHURCH, F.R.S.

FRIDAY, June 12th.

PHYSICAL SOCIETY OF LONDON.

5 p.m. Papers to be read: (1). "Ultimate Current and Potential Difference Analogies in the Methods of Measuring Power." By Prof. W. E. Ayrton and Dr. W. E. Sumpner. (2). "A Clock for Pointing out the Direction of the Earth's Orbital Motion in the Ether." By Prof. O. Lodge, F.R.S. (3). "Some Experiments with Leyden Jars." By Prof. O. Lodge, F.R.S. (4). "The Construction of Non-Inductive Resistances." By Prof. W. E. Ayrton, F.R.S., and T. Mather.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "The Rate of Explosion in Gases." By Prof. Harold Dixon, F.R.S.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing, and Printing Offices:
SALISBURY COURT, FLEET ST., LONDON, E.C.
Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co*" *All Editorial letters to be addressed to the Editor.*

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from Publishing Offices as above.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

SUBSCRIPTION RATES.

The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months	6 months.	12 months.
	s. d	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
For Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements should be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday.*

SMALL PREPAID ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1891 Edition, published on the 23rd February, 1891, consists of 900 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with well-written Biographical Notices of leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1891 should be ordered at once. Price 5s., post free 5s. 9d. Abroad postage extra. Prospectuses free.

ELECTRICAL BOOKS AND PUBLICATIONS

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

"THE ELECTRICIAN" *Series at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING. Vol. I. Price 7s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Vol. I. Price 6s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

Several Further Volumes in Active Preparation.

NEARLY READY, IN TWO VOLUMES.

"THE ELECTRICIAN" PRIMERS.

Fully Illustrated.

Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

ELECTRIC SUPPLY FROM CENTRAL STATIONS.

The subject of the distribution of electricity "by means of gas" is dealt with in some interesting notes by the *Journal of Gas Lighting*. Our contemporary is of opinion that this method should be seriously considered in connection with the municipal electric lighting of Glasgow, and in discussing the question alludes to some editorial notes in the concluding number of our last volume. We are said "to admit that where light is wanted on a tolerably large scale 'it is undoubtedly cheaper to put down the generating plant than to make use of the energy provided by the supply companies,'" and we are told that "this admission means nothing less than the total contradiction of the views expressed ten years ago with such confidence by the late Sir W. SIEMENS . . . . We were then told that nobody could expect cheap electric lighting until huge stations were established, supplying current generated by engines of the largest size and most economical type. Well," continues the *Journal of Gas Lighting*, "we have such generators in a dozen places, and yet *The Electrician* confesses that the little private stations in the City and West-End, where gas engines run the machinery, 'have no difficulty in generating a unit for 4d.'"

We feel tempted to go even further with the admissions and confessions to which our contemporary refers, but prefer at present to wait until the supply companies have shown us what they can do. We would point out that it is as yet by no means customary in central lighting stations to lay down "engines of the largest size," indeed it has only been done up to the present in one instance, and it is generally spoken of as a huge experiment—but this is a mere detail. We will, however, make one more concession which may please our contemporary, and that is, that the gas engine is a machine of such admirable economy compared with a steam engine,

Digitized by Google

that if electricity is to be generated on a moderate scale there is no better means of doing it than "by means of gas," and there is, in our opinion, a great deal to be said for the method of distribution which it advocates so forcibly. The idea of sub-stations has a fascination for many electrical engineers, and where, as at Glasgow, the gasworks are in the hands of the municipality, if the gas mains are large enough, the sites easily obtainable, and if no trouble arose from noise and vibration, and—one more "if"—if the cost were really low enough, the advantages would be very considerable. Indeed, were it not for some of the figures given in Mr. CROMPTON's recent Paper, and the satisfactory way in which they were corroborated by Mr. WILLANS and others in the discussion, we should be inclined to "confess" that the economic results of the supply companies, as indicated by the price of the unit and by their balance-sheets, are rather discouraging. We allude here merely to the apparent cost of production and to the cost of distribution. It can be shown on paper that the engine-room expenses may vary from one penny to one halfpenny per unit, and that the total cost of production and distribution may be as low as twopence farthing, with an output of 800,000 units. In his Paper before the Institution of Civil Engineers, Mr. CROMPTON boldly gave the ideal figures of coal consumption at which he aimed, and as frankly confessed how far short he fell from them at present. Although no advocate of alternating currents has ventured to publish the coal consumption on the transformer system, it is generally admitted that they cannot yet compete with low-pressure supply in this respect, but no conclusion can be arrived at until the substation system of cutting out transformers has been thoroughly tried.

There are two chief points to be considered, production and distribution. Sir WILLIAM SIEMENS, rightly or wrongly, expressed the view that the larger the scale of operations the less would be the cost of electrical energy, and the fact that certain marked economies were observed as soon as the load was transferred from the Grosvenor Gallery to the generating plant at Deptford may be adduced in support of this view. But it must be remembered that we do not turn out electrical energy from a supply station in the same way that steel pens or woollen goods are produced in a factory. The reasons for the economy of production on a large scale in ordinary manufacture are sufficiently obvious, and consist largely in the saving of wages by specialisation or "division of labour," and by the mere extension of the use of machinery. But electrical supply companies, while they do on a large scale what many a householder does on a small scale, employ exactly the same methods, but with an enormous increase in labour. They employ large dynamos which are designed on very similar lines to the little machines, and they use accumulators of precisely the same kind. The economy of the large dynamo by reason of its higher efficiency is a mere trifle in the present comparison. The householder employs practically no labour. A domestic starts the engine and lets it run, and a mechanic looks in once a week at the most, to see that all is working smoothly. The householder has no costly mains, no wasteful transformers, no additional rent, and no staff of engineers, clerks, no directors and shareholders. No wonder then that he can compete with the supply company, and the only drawback is the trouble, and, in the case of anything but the very best machinery, the noise and vibration. One result, therefore, of the last breakdown at the Grosvenor Gallery was that several customers of the London Electric Supply Corporation put in their own machinery, for, after once having enjoyed the benefits of the electric light, no one will return to gas or oil if he can help it.

The economy of production on a large scale, then, is more than counterbalanced, as far as cost is concerned, by the expense of distribution and management. In all the balance-sheets which have hitherto been published, the item "labour" has mostly been charged to capital, since the supply companies are engaged in extending their works, and it is difficult to estimate the staff which will be required when they have settled down to a simple supply business. The two directions in which "distribution by gas" would save money, are first, in the coal consumption, and this, not only by the saving of so many tons of coal, used to get up steam, etc., and the theoretical losses of the steam engine, but in the utilisation of the numerous residues for which a good market has been created, and secondly, in the absence of trunk mains and feeders, since the existing gas mains, relieved to some extent from the demand for gas for illuminating, should without difficulty supply the gas engines for generating electrical energy. The enormous discrepancy between the 2½ lb. of coal at which Mr. CROMPTON aims, and the 10·7 per unit delivered, which he burns in practice, or even the 8·88 lb. per unit generated, to say nothing of the 17 lb. which the alternate current stations are said to use, is, we believe, largely due to waste in the boilers, and this partly because space is so valuable that really economical boilers are very rarely put down, and because they are used for so few hours during the day. No difficulty of this kind arises when gas engines are employed, and now that the makers are being induced to build engines of 200 H.P. a favourite size in supply stations, but too large for sub-stations, no difficulty need be apprehended as to the practicability of the system. But our contemporary talks as glibly of the Glasgow Corporation being "accommodated, at a reasonable rent, with a cellar into which they could put a couple of engines and the necessary electrical plant" as does Mr. GORDON whose requirements are far more moderate, but who is assured by his critics that cellars are not so easy to get.

The Glasgow Corporation have got into a sad muddle through making the mistake, in the first instance, of consulting a contractor as to what, in his opinion, would be the best system to adopt in Glasgow, instead of confining themselves to a request for estimates. The city authorities applied to the Local Board for permission to raise, for electric supply, the largest sum on record, and yet they have been unfortunate enough to confuse a contractor with a consulting engineer. Mr. CROMPTON has acknowledged that a length of 2,400 yards is his favourite maximum length of feeder, and it happens that the excellent sites at Partick and Dalmarnock are beyond this distance. It is only natural, therefore, that he should advise a central station. Had the Corporation consulted an alternating-current contractor of equal eminence, experience and success, if such an one there be, they would, of course, have met with so completely contradictory advice that they must have seen at once the folly of asking a contractor for anything more than an estimate. They have, however, sought counsel from scientific professors and from their own gas engineer, and have some half-dozen tenders; and, now, the *Journal of Gas Lighting* volunteers its advice on the subject. Electric light is no more likely to supersede gas than steam locomotion to supersede horses. As a matter of fact, the Midland and the London and North-Western Railway probably own more horses than were to be found in England at the time of the introduction of railways. It is possible, therefore, that after an equal lapse of time, if our contemporary has not changed its title to the *Journal of Gas Engineering*, it may still, in an indirect way, retain its present name through having encouraged the idea of distributing the electric light by means of gas.

OBITUARY.

DAVID BROOKS.

We regret to have to record the death of Mr. David Brooks, who died at Philadelphia on Sunday last.

Mr. Brooks was born on January 26, 1820, at Brooks Vale, Conn. At the age of 20, David Brooks left college, and took a position of instructor of mathematics in the United States Navy. In 1845 he left the service, and engaged, with his friend, Henry O'Reilly, in the construction of telegraph lines. During that year he, in conjunction with James D. Reid, put in operation the first telegraph line in America, after the success of the original line between Baltimore and Washington had been established. This line was between Lancaster and Harrisburg. In the following year he constructed the line between Philadelphia and Pittsburg, a distance of 360 miles, crossing the Allegheny Mountains. In 1847 he constructed the first "repeater." This was used at Pittsburg and Philadelphia in the transmission of the speech of Henry Clay, on the Mexican War, at Lexington, Kentucky. The report of that speech was carried by express, which consisted of a relay of horses, to Cincinnati, and transmitted from Cincinnati to New York by telegraph, for the *New York Herald*, and was considered a remarkable feat in telegraphy. The arrangement of the repeaters, and Mr. Brooks' connection with the work, brought his name prominently before the telegraphing public.

In 1850 Mr. Brooks was appointed by the United States Court to give a written description of the Morse and Bain system of telegraphy, and in the voluminous report of the attendant trial his statements and opinions are repeatedly cited. In July, 1851, he sailed for Mexico, in the barque "Rosina," taking with him men, materials, and instruments for the construction of the first telegraph line in that country, between Vera Cruz and the City of Mexico. The work was accomplished during the ensuing six months. Upon Mr. Brooks' return from Mexico, in 1852, he was employed by the Pennsylvania Railroad Company in the construction and management of their telegraph lines between Philadelphia and Pittsburg. In 1854, Mr. Brooks was made superintendent and managing director of the Atlantic and Ohio telegraph lines. This company was absorbed by the Western Union in 1862, and Mr. Brooks remained with the latter company as district superintendent until 1867, when he resigned.

Of late years Mr. Brooks had identified himself with the use of oil insulation, and only a week or so since he was vigorously advocating its virtues in the American electrical journals. The first oil-insulated cable on the Brooks' system was laid in London in 1880. Paraffin oil was used, and considerable difficulty was experienced in keeping it in the pipes. Rosin oil was then substituted, and no further trouble was experienced from this cause. Since its first introduction oil has come into extensive use as an insulator, its latest application being to high-pressure transformers.

ELECTRIC AND MAGNETIC THEORIES.

BY SILVANUS P. THOMPSON, D.SC.

(*Continued from page 105.*)

§ 15. Energy being a quantity which can be definitely transferred from one part of space to another, and being capable of holding a definite existence in intermediate space when that space is occupied by a medium in a state of strain, there is nothing illogical or unphilosophical in the proposition that the energy-paths possess definite configurations, which can be investigated, and, in many cases, discovered. In the argument which follows nothing is taken for granted beyond matters involved in the usual definitions. If a unit of electricity is moved through an electric field from a point in space where the potential is high to a place where the potential is low, work is done by this unit in so passing; and if not spent in overcoming resisting forces *en route* may be utilised entire at the point of arrival. The energy which was potential at the first point may be in some other form on its arrival at the second point—the precise form of it is not now the question under discussion—that it has been transferred along a definite path there can be no manner of doubt. Nor need we actually suppose any electrified particle itself to travel along the energy path. Energy may be transmitted across a dielectric medium without any portion of that medium actually moving from one side of the space to the other. When heat is transmitted along a metal poker, or sound along a wire, no one supposes the metal particles to travel along the path of the heat or the sound. When light crosses from the sun to the earth, no one supposes that the hot solar atoms shoot across space. When sparks appear between the tips of the Hertzian exploring circuit, no one supposes these sparks to have been conducted across the medium from the oscillator; they have been set up as the result of energy which crossed the medium by invisible paths. If energy paths exist in the case of rapidly-varying currents, why not in the case of steadily-flowing currents; even though in the latter case we have no direct evidence to prove their existence?

§ 16. The medium surrounding a wire that is a part of an electric circuit is the seat of a double set of actions. Its electric potential varies from point to point, the medium being in a state of electrostatic disturbance. It is also in a state of maguetic disturbance, and its magnetic potential varies from point to point, but in a wholly different manner. For the sake

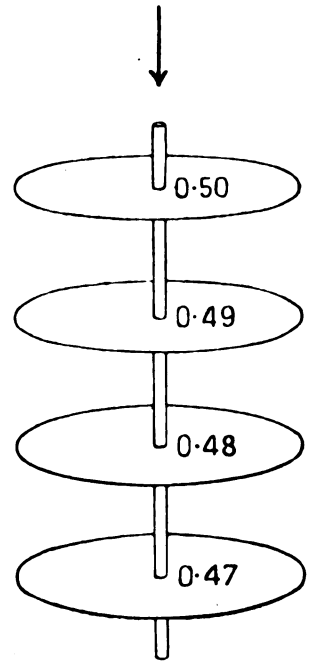

Fig. 12.

of simplicity let us consider an indefinite long straight wire, through which a "current" is passing. For the sake of numerical precision, suppose the wire to have a resistance of $\frac{1}{100}$ ohm per inch, and a current of 1 ampere to be passing through it. Then points distant an inch apart along the wire will differ by $\frac{1}{100}$ of a volt. Select one of these points where the potential has the value, say, of 0·50 volt. Through this point consider a plane drawn so that the wire is normal to it. All points in this plane will be at the same potential: the plane will be a surface of equipotential. No energy need be spent in moving a unit of electricity from any point in this plane to any other point in it. At other points along the wire let similar equipotential surfaces be drawn, as in Fig. 12. The lines of electrostatic force will be straight lines drawn parallel to the wire, and will cross the equipotential surfaces normally. But surrounding the wire will be another system of lines and surfaces, mapping out the magnetic properties. Consider any point P near the wire. On a unit magnetic pole, at a distance of r centimetres, the force due to the one-ampere current will be equal to $0{\cdot}2 \div r$ dynes, and will tend to move it (as viewed in Fig. 13) clock-wise around the wire. If we push it the opposite way around we shall do work upon the unit, and when we have pushed it once completely round the wire we

Digitized by Google

shall have done $2\pi \times 0{\cdot}2$ ergs of work; or to move it through an angle of one radian ($= \frac{1}{2\pi}$ of a circumference) will require an expenditure of 0·2 ergs of energy. A plane drawn through P and the wire will be a plane in which all points are at the same magnetic potential. A system of such magnetic equipotential surfaces may be drawn around the wire; they will be set radially, at equal angles apart, reckoning from the zero position. For a current of 1 ampere the angle between

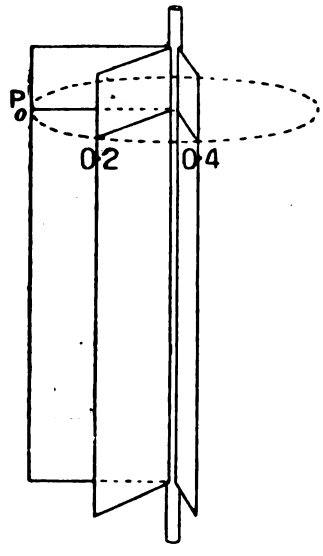

Fig. 13

surfaces that differ by $\frac{1}{10}$ of a unit of magnetic potential will be equal to $\frac{1}{4\pi}$. Now, imagine these two systems of surfaces to be superposed. The intersections of the electrostatic equipotential surfaces with the magnetic equipotential surfaces will be a set of radial *lines* (Fig. 14). Now consider what would happen if we had to move either a unit of electricity or a unit magnetic pole along one of these lines, such as P Q. Because the line is in a surface of electrostatic equipo

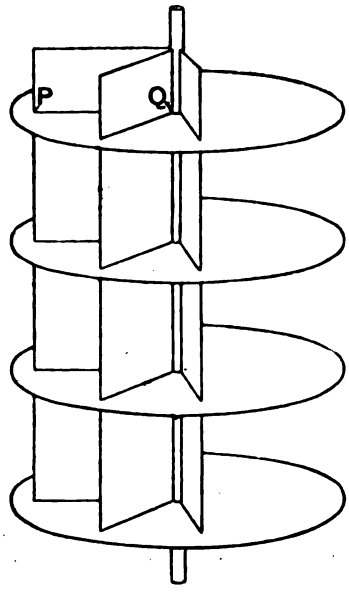

Fig. 14.

tential, no work would be done along the line in question in moving a unit of electricity along it; and because it lies in a surface of magnetic potential, no work would be done in moving a magnetic pole along it. Now, according to Poynting's view, it is precisely along such lines as these—the intersection of the static and magnetic equipotential surfaces—that the electro-magnetic energy flows. It is the only path compatible with the condition that the energy in crossing the medium shall not either add anything or take anything away from the energy already existing in the medium. If it were to leave this line, and pass either to a point of higher or lower potential in the medium, this would alter the state of the medium and change the configuration of the electrostatic and electro-magnetic stresses in it. That is, of course, exactly what happens during the time when an electric current is starting, during the variable period, while energy is being poured out into the medium to throw it into the peculiar state at the beginning. But we have been dealing here with the question of steady flow.

§ 17. Again, in the case of alternating currents setting up alternating electromotive forces across the medium in another circuit, during part of the oscillation some energy is being thrown outwards into the medium simply to set up stresses, and some more energy is actually crossing, by the paths so set up, into the second circuit; and during another part of the oscillation the energy that was momentarily resident in the medium is re entering the source to be again thrown out. Doubtless the energy paths are of somewhat complex form in all these cases; that is no reason why their real existence should be held doubtful. Take a single case. Consider a system of circuits with two interposed transformers; one transforming from a primary circuit into a secondary, the other transforming from the secondary circuit into a tertiary. How complex must be the paths here along which the energy flows, even if one confines one's attention solely to those parts of the circuits where the transformations are taking place! And yet one knows well that energy is being transferred, and that it must go along definite routes, and that these routes are not the copper wires, because here the great fact is that the energy is passing across, *viâ* the interposed magnetic medium, from one circuit to the other. The fact that the routes are complex does not prevent their being real. How complex, for example, are the paths by which the water in front of a ship streams round to the region behind it as the ship sails forward; yet no one doubts, because of their complexity, that such paths definitely exist.

(To be continued.)

ELECTRICAL INSTRUMENT MAKING FOR STUDENTS.

THE LINESMAN'S "DETECTOR."

In these occasional articles describing the design and construction of the apparatus commonly used by students and others, mere appearance will be ignored, and attention will principally be directed to efficiency and simplicity of construction. Although *mere* appearance will not be insisted upon, it must not be forgotten that neatness is everything in instrument making, as in most other handicrafts, and a little extra care and trouble bestowed upon an instrument often go a long way towards increasing its utility. It may be as well, therefore, to keep the following suggestions in mind, as they may save an appreciable amount of worry. Always keep your tools and implements sharp and in good condition. Never put anything away unless it is ready for use next time it is required. Do not mix nails, rosin, and silvered mirrors indiscriminately together; cardboard boxes are inexpensive, and it will save time and expletives to have a separate deposit for each class of article. Never consider a job done as long as you are capable of improving upon it.

The most generally useful and in fact indispensable of all electrical instruments, is the ordinary linesman's "detector," and as this instrument will be found useful in the construction of others, it will perhaps be as well to begin by describing a useful and easily constructed form.

Fig. 1 is a front elevation; Fig. 2 is a plan, the top being removed, and Fig. 3 a side elevation, the side being removed; *a a* is the outer case, 4in. × 4in. × 1¾in. outside measurements. This should be constructed of good close-grained wood, preferably mahogany, ¼in. thick; the top, bottom, and sides should be glued and fixed with brass screws, while the back (*a'*) should be merely screwed so that the inside of the instrument may be

Digitized by Google

always get-at-able. It may be as well to mention in this connection that the use of iron nails and screws and of iron or steel generally should be avoided as much as possible in electrical instrument making, except, of course, where their magnetic properties render their employment advisable, as errors and mistakes may thereby be avoided. The glass front of the instrument *b* is about 3¾in. square by about $\frac{1}{16}$in. thick, and is let into a recess formed for it by cutting away the inside edges of the case to a depth of half the thickness of the wood (viz.,

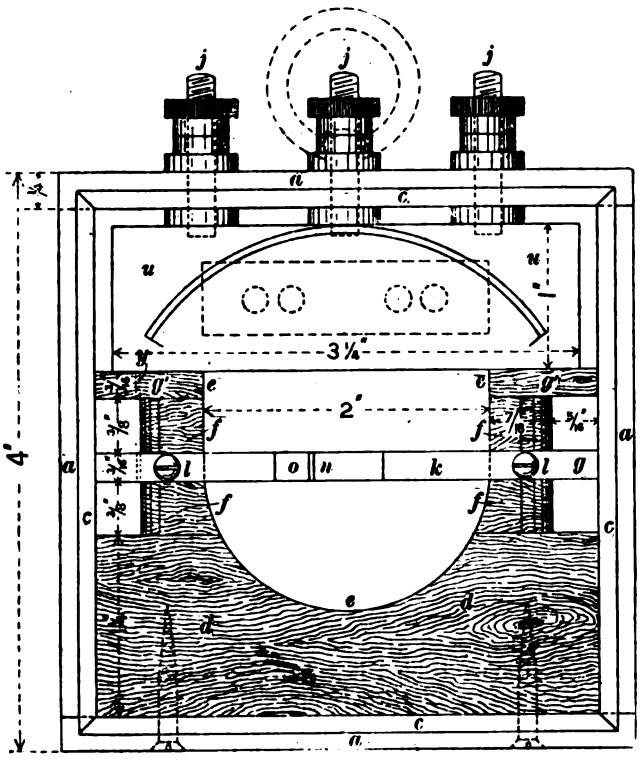

Fig. 1.—Front Elevation.

$\frac{1}{8}$in.), and a width of about $\frac{3}{16}$in. from the edge; these recesses must be neatly formed with the assistance of a tenon saw and chisel, their widths and depths having been carefully marked with a gauge. The glass is dropped into the recess so formed after the case is put together, and is fixed by filling in the angles, *c c*, with sealing-wax (preferably black); this should be neatly melted into the corners with a hot strip

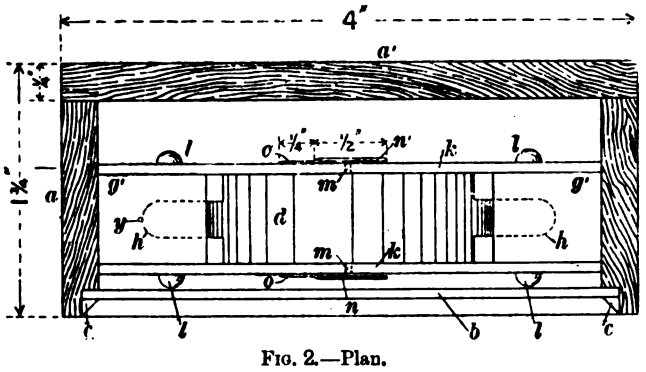

Fig. 2.—Plan.

of metal, and the superfluous sealing-wax removed from the glass with a little methylated spirit as soon as the cementing has hardened.

A piece of wood, *d*, 3½in. × 2⅜in. × $\frac{5}{8}$in., with the grain running longwise, has the semi-circular space, *e e*, cut away with a fret saw to receive the needle system; *f f* are recesses cut with a tenon saw and chisel. These should be $\frac{3}{8}$in. wide, $\frac{3}{16}$in. deep at the sides, $\frac{5}{16}$in. deep at the ends, and should be $\frac{7}{16}$in. apart, leaving a flange, *g*, between them and another flange *g'*, $\frac{3}{16}$in. thick at the top of the block, *d*; the corners of the grooves should be rounded off with a file, as shown at *h h* (Fig. 2); *i* (Fig. 3) is a drawer ring for carrying or suspending, which may be purchased at any ironmonger's; *j j* are terminals, and *k k* are brass strips for supporting the needle system; they are 3½in. long by $\frac{3}{16}$in. wide, by about $\frac{1}{16}$in. thick, fixed at the ends by screws, *l l*; these screws should be No. 3 round-headed brass screws, $\frac{3}{8}$in. long, and care must be taken in putting them in not to split the wood. The best way of preventing this is to drill holes in the wood to receive them, just sufficiently

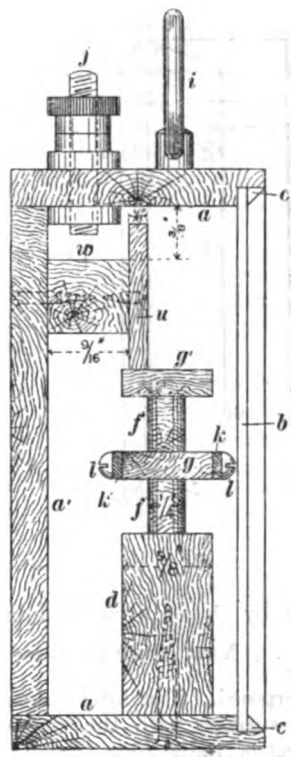

Fig. 3.—Side Elevation.

small for them to bite in. At the centres of these brass strips, *m m*, are two holes just large enough to receive a No. 6 needle without much side-play. *n n* are two strips of very thin brass, soldered at *o*. The use of these is described below.

Now as to the needle system. This is shown in elevation in Fig. 4, and in plan section in Fig. 5. *p* is a piece of brass rod $\frac{3}{16}$in. in diameter, and a little over ½in., say $\frac{9}{16}$in. long, with a hole drilled through it a shade nearer one end than the other, and of sufficient size to receive a bit of steel rod, *r*, 1⅞in. long by about $\frac{3}{32}$in. in diameter, which is to form the magnetic needle of the instrument. This piece of steel should be made dead hard, and cleaned; it should then be placed on a bit of

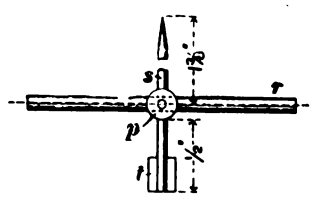

Fig. 4.
Needle System. Elevation.

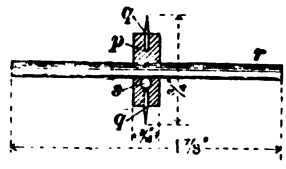

Fig. 5.
Needle System. Plan Section.

sheet brass, and held over a flame until it begins to turn a light straw colour, when it should be again chilled. The centre should be sufficiently cleaned to take solder. After having been magnetised as strongly as possible, the steel needle should be pushed through the hole drilled for it in *p* until it projects equally on either side (if the hole is too loose to hold it firmly, it should be slightly close by tapping the edges with the riveting side of a hammer). As soon as the needle is in its proper position it should be lightly soldered at each side of *p*, care being taken to make the soldering-bit thoroughly hot, in order

Digitized by Google

that the solder may run before the heat reaches the ends of the needle. As each side is soldered, the whole should be dipped into water and cooled. Having fixed the needle, a hole should be drilled through p exactly at right angles to r, to receive the pointer s. The pivots $q\,q$ are the pointed ends of two No. 6 needles, cut off to the right length, and having their points slightly blunted. These are pushed into holes drilled for them in the exact centres of the ends of p. The best way to make these holes concentric and of the proper size is to drill p through from end to end with a No. 6 needle made into a drill. The pivots may be firmly fixed into the holes thus made for them by clamping p in a vice, and tapping the brass round them with a small cold chisel and hammer in such a manner as to close the holes round them. The distance between the points of the needles should be such that they do not touch both the stops $n\,n'$ at the same time; these stops are to prevent the ends of the brass piece p from rubbing against the brass strips $k\,k$. The pointer s is a piece of No. 16 hard brass wire about 1½in. long, pointed at one end, and screwed into the block p, and having a short piece of the same wire with a counter-balance of brass soldered to it, screwed into the block, on the under side. This counter-balance should be of just sufficient weight to bring the pointer well to zero after the instrument has been tilted.

The pointer must be fixed, and the needle system placed in position after the wire is wound in its grooves. This is effected in the following manner: Having given the block d a coating or two of shellac varnish, and having thoroughly dried it, proceed to construct a "former" of wood ¼in. thick, which must just fill up the space $e\,e$, and project a little above the flange g'; the surfaces of this former must be quite smooth, and it should be soaked for a few minutes in hot paraffin wax to prevent the wire from sticking to it. This former must be fixed in the space e in such a position that its sides are flush with the bottoms of the grooves $f\,f$. Now wind neatly and smoothly in each groove two layers of No. 16 B. W. G. double silk-covered copper wire. The outer end of the wire in the top groove should come through a hole in the flange g', shown at y, Fig. 2, and the wire should pass from the top groove to the bottom groove through a hole in g in a line with y. As soon as the wire has been wound on it should be varnished with shellac varnish, and covered with a layer of stiff note-paper, which must form a fresh surface for the fine wire coil which is next wound on. This should consist of No. 36 or 38 single silk-covered copper wire; the wire must be laid on as smoothly and evenly as possible, and each layer as it is finished must be varnished with thick shellac varnish. As soon as the grooves are quite full of wire the whole must be thoroughly dried, after which the "former" must be carefully extracted and the needle system fixed in position.

To perform this operation proceed as follows:—Screw on one of the brass strips k, and place one of the pivots in position in its pivot-hole m; next screw the counter-weight half-way through the hole made for it in p, and allow it to drop into the recess e. Then screw the pointer s into the other side of q with a pair of pliers, taking care neither to bend it nor to put any strain on to the pivot; the other brass strip may now be fixed in position, when the needle system should swing freely. The whole may then be fixed into the case as shown. The graduated scale of the instrument is drawn on smooth paper. A piece of cigar-box wood, u, 3¼in. by 1in., is fixed to a block of wood, w, screwed on to a', which must be of sufficient thickness to bring the scale close to the pointer. The scale should be held to u by means of drawing-pins until its proper position has been found, when it may be fastened with a little thin glue, and dried under a weight, care being taken that the scale is not shifted. The ends of the coils should be carried up the sides of the case and soldered to the terminals, connection being made as shown in the diagram, Fig. 6. It will be seen from this diagram that the thick wire coil is between terminals 1 and 3, and the fine wire coil between terminals 2 and 3; when terminals 1 and 2 are used the two coils are in series acting in the same direction. The case should be varnished both inside and out, and a coat of transparent varnish on the scale itself protects it from dirt, and renders it capable of being cleaned.

OPENING OF THE NOTTING HILL COMPANY'S CENTRAL STATION.

On Saturday afternoon last Prof. Crookes presided at the opening of the Central Station of the Notting Hill Electric Lighting Company, in Bulmer-place. Some hundreds of the Notting Hill residents and others were present at the ceremony.

The Notting Hill Company has adopted the three-wire system of distribution, the Crompton system of mains being employed, and at present about 3 miles of culvert, containing more than 40 tons of copper strip, have been laid. The Company was obliged, however, owing to cellars under the pavement, and not therefore having sufficient room, to revert to cables, and about 6 miles of cables in iron pipes have been put into the ground. With regard to the station, the Company has had the ground excavated for the boilers and engines, and the floor line is 22ft. below the street level. The dynamos stand on a concrete bed, and, to avoid vibration, this concrete bed has been isolated from all parts of the structure. The plant now put down consists of three Willans and Robinson engines, coupled direct to Crompton dynamos of the newest type; that is, two G.G. engines coupled to 50-kilowatt machines, having drum armatures, and one I.I. engine coupled to a four-pole dynamo, having a capacity of 120 kilowatts. There is room on the concrete bed for five more large sets. The boiler plant consists of two Babcock and Wilcox boilers, each of 350 H.P. capacity, and two semi-portable ones of the locomotive type of about 75 H.P. each, by Messrs. Marshall and Co. The Babcock and Wilcox boilers are fitted with purifiers, which receive the water from two Worthington pumps through a water heater. In the accumulator room there are two sets of Crompton-Howell batteries, each consisting of 56 cells of 61 plates, having a capacity of 500 ampere-hours. The switchboard controlling engines and dynamos was manufactured by Messrs. Crompton and Co., and is an exact counterpart of the one at the Kensington and Knightsbridge stations.

The number of lights applied for before the opening of the station was about 5,000. Of these, 2,500 have already been connected, and the remainder are being put on as fast as possible. When this station has its full complement of boilers, engines, and dynamos, it will be able to supply 25,000 lamps of 8 c.p., alight simultaneously, and, as all the lights connected are never alight at the same time, the station can deal with houses wired for 50,000 lamps.

It is the intention of the Notting Hill Company to immediately build another station for the southern portion of Notting Hill, and also a battery station for the portion of the district furthest from the present central station.

A detailed report of the opening proceedings will be found in a subsequent page.

ON SOME POINTS CONNECTED WITH MAINS FOR ELECTRIC LIGHTING.*

BY WILLIAM HENRY PREECE, F.R.S., PAST-PRESIDENT.

(Concluded from page 111.)

21. Such being the distribution of potential on a concentric main, and also on a system of two parallel conductors, it is now desirable to compare their relative security. We have to consider, not alone what happens when everything is in order, but what happens when accidents and faults arise. Nothing is perfect—we have only before us a choice of evils. Earth is the electrician's bane, but there may be circumstances under which it may become his antidote. No one but Mr. Ferranti has had the temerity to employ the earth as his antidote, and I must confess that I have been compelled to effect a compromise with him on the subject. His original form of cable was designed so as to place the outer tube completely to earth, but my own experiments† and his experience have shown that this outer tube must be thoroughly well insulated to prevent the introduction of serious disturbing effects on telegraphs and telephones. In Rome, where Siemens concentric cables are largely used, but without earth, the outer insulator was so frequently

* Paper read May 7, 1891, before the Institution of Electrical Engineers.

† "On the Disturbances arising from the Use of Earth for Electric Lighting Purposes," March 28, 1889.—*Journal*, Vol. XVIII., p. 314.

Digitized by Google

pierced that Prof. Mengarini found it necessary to make the outer insulation thicker and better than the inner. The sudden stoppage of a flow of great energy from any cause must lead to effects analogous to those of momentum, and unless some buffer or cushion is provided, either in the form of a condenser or of the earth, a heaping up of pressure must occur somewhere, and sparking and rupture follow.

22. Mr. Ferranti claims for his concentric mains with the outer conductor earthed at one end, as shown by Fig. 11 :—

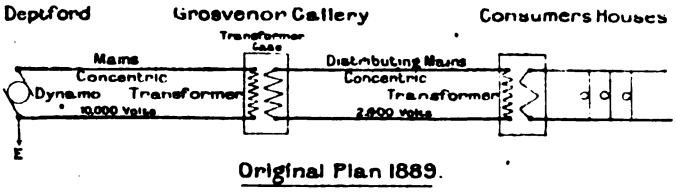
1. Absolute safety in handling by workmen, and freedom from fire risk.

2. Dispersal of the static charge accumulated on the conductors.

3. Freedom from disturbance on neighbouring wires.

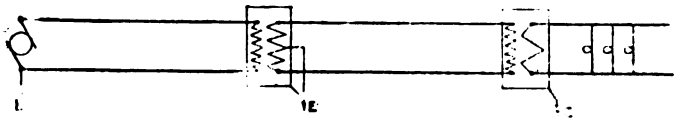
I can corroborate the last point. We in the Post Office are now quite unaware whether the Deptford mains are at work or not. It was not always so. At first, starting with imperfect cables, the disturbances were very serious.

The compromise effected between the Postmaster-General, the Board of Trade, and the London Electric Supply Corporation is shown by Figs. 12, 13, and 14, which also give some of the changes that have been made.



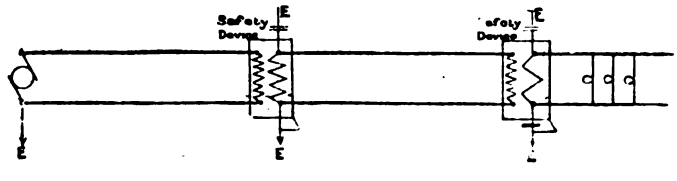
Original Plan 1889.

FIG. 12.



In use November 1890.

FIG. 13.



Authorised 1891

FIG. 14.

We allow earth on the outer conductor at Deptford, and at each distributing station, but not on mains other than concentric, or on the house service, excepting through a safety device.

With regard to high-pressure alternating-current systems generally, earth cannot be admitted on house wires, because with its use high insulation is imperative to reduce fire risks, and high insulation cannot always be maintained. Leakage means danger, in spite of fuses and safety devices. Fire and life risks are intensified by bad earths. Good earths are very difficult to secure, and alternate currents do not like earth—that is, the resistance of earth to alternate currents is much greater than that to direct currents.

We can secure safety in houses by—

1. Good materials.
2. Good workmanship.
3. High insulation.
4. Well-designed safety devices.
5. Frequent tests.
6. Incessant personal supervision.
7. NO EARTH.

In the wiring of houses supply companies and corporations cease to exercise responsibility. They deal with confiding customers, irresponsible contractors, untechnical and uneducated employés, and all sorts and conditions of men. Were it not for the Board of Trade to regulate our mains, and the Fire Insurance Companies to regulate our house wires, electric lighting in England would be as dangerous a pursuit as it appears to be in the United States.

23. The Board of Trade has forbidden the use of earth on separate conductors. This is absolutely necessary, for, except with concentric mains, the use of earth on one conductor might be exceedingly dangerous if the other conductor, by fault or otherwise, made earth. The inner conductor of a concentric main is so hermetically sealed, and so thoroughly protected by a succession of coatings, that it is well-nigh impossible for a leak to earth to be caused on it. Faults would take the form of a short-circuit, not of earth. A system to earth is one which has been placed at full cock ; a permanent fault has been put on intentionally. Equilibrium has been disturbed, and it is the security of the inner conductor of the concentric main that alone makes it acceptable.

24. The chief accident that one has to fear in the high-pressure alternate-current system is the piercing of the insulating medium between the primary and the secondary conductors of the transformer, and the formation of a contact between the two. Such a fault admits the high-pressure into the low-pressure system, and has been the source of nearly all the troubles that have arisen. Earthing the conductor puts a great strain on this medium. Risks of fire are increased. Additional preventive measures are necessary, and hence safety devices—the best at present in the market being Major Cardew's.

The use of safety devices which earth the conductor *at once* when the transformer is pierced, or when high pressure enters the low-pressure system, is, in my opinion, an absolutely necessary safeguard, and I never issue any specification without requiring Cardew's device, which is thoroughly effective and reliable.

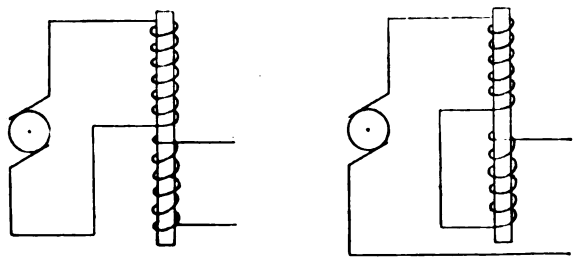
25. The use of low or of high pressure should not be a question of opinion or of objection. The supposed waste, danger, and difficulties of the one are disappearing under the able tuition of experience ; while the complicated regulation and variable distribution of the other are submitting to inventive skill. It is now a question of calculation and of finance. The only variable is the number of feeding points. The determining cause and the uncertain element is the density of lamps per acre or per mile of street. We start with this initial difficulty—that we do not know our customers, and we have to prepare for a visionary *clientèle*.

This Paper has been a little discursive. Its principal object is to direct attention to the simplicity of the two-wire parallel system of distribution, to the security of the concentric main, to the devices to promote the safety of the high-pressure system, and, above all, to the necessity for regarding the whole question from the engineering maintenance point of view rather than from that of the speculative promoter.

The following is the authorised abstract of the discussion which followed the reading of Dr. Fleming's Paper "On Some Effects of Alternating-Current Flow in Circuits having Capacity and Self-Induction."

DISCUSSION.—THURSDAY, MAY 14TH.

In opening the discussion, Mr. SWINBURNE said he was particularly interested in the subject dealt with in the Paper, for he considered it a most important one, and believed he himself was the first to suggest the true explanation of the phenomenon known as the Ferranti effect. When the effect was first observed it was looked upon as peculiar, and various authorities were exercised in finding an explanation. In December last, when he read a Paper on alternate current condensers before the Physical Society, no authoritative statement as to what actually occurred had been published, but he took the conditions and worked backward to see what the effect ought to be. He then found that putting a condenser on the



Elementary diagram of transformer, primary and secondary wound 1 to 1 ; and the same transformer with the coils connected in series, merely producing a "drop."

secondary mains would increase the pressure, and explained the rise by the action of the "leading" condenser current on the magnets of the alternator. Whether the rise might be said to be due to armature reactions or to self-induction was chiefly a question as to what was meant by self-induction. Several persons had attributed the "Ferranti effect" to the

Digitized by Google

transformers, since the rise did not occur when the transformers were not interposed between the alternator and the trunk mains. This difference he showed to be caused by the condenser current in the alternator being four times greater when the transformers were on, and in addition the field magnets were only about one-fourth as strong, so that they were more easily influenced by the condenser current. He himself thought any rise due to the transformer would be small, but Dr. Fleming had found it fairly large. This was probably owing to the comparative smallness of the transformers used, for in very large transformers such as he assumed were employed the magnetic leakage to which he (Mr. Swinburne) attributed any rise caused by the transformer was relatively small. He ventured to think that Dr. Fleming had made a mistake in imagining the self-induction of the primary of a transformer an important factor in the phenomenon, for it could only act as a choking-coil in consequence of the magnetic leakage which existed. Part of the increased pressure was due to the "drop" in the transformer, and in designing transformers this drop should always be determined and allowed for. After giving a formula suppressing the drop in open circuit transformers, he said that Prof. Ayrton had found that there was a rise of pressure due to the transformer, and had also stated that a rise occurred in the mains themselves; this he (Mr. Swinburne) had shown to be impossible. He hoped Dr. Fleming would go into the subject of transformers more fully, taking the waste field into account. Unfortunately, this leakage was at present considerable, but he thought it would soon be reduced.

Prof. AYRTON said he took great interest in Dr. Fleming's Paper, because it confirmed many results brought forward by Dr. Sumpner and himself in a Paper recently read before the Physical Society. Referring to paragraph 6 of Dr. Fleming's Paper, he said that the general statements about Mr. Blakesley's conclusions and those of the author were rather confusing, for Mr. Blakesley's results were only applicable to shunted condensers, whereas those of Dr. Fleming referred to unshunted condensers. In treating of Resonance, the author, he said, concluded that there was only a narrow range of capacity within which the pressure at the condenser may be much greater than that at the machine. This conclusion resulted from his having chosen a coil having a resistance of only 10 ohms, and a very large self-induction of 200 secohms (henrys). As a matter of fact, resonance effects spread over a large range, and in practice it was impossible to get a coil with such a large time-constant as Dr. Fleming had imagined. The pressure at the condenser could, therefore, never be 100 or 1,000 times that at the alternator, 5 or 10 times being about the practical limit. The experiments made by Messrs. Siemens Brothers are very interesting, and distinctly proved that the ratio of transformation of a converter varied with capacity. No doubt Mr. Swinburne would say it was all due to leakage, but, nevertheless, the fact that the change existed was certain. In some experiments which Dr. Sumpner and himself had brought before the Physical Society a change of 11 per cent. was observed when the ratio of transformation was only 2, and it was then pointed out that with larger ratios the changes would be greater. In the case of the Siemens transformer the ratio increased 32 per cent. Referring to the mathematical equation No. 31 in the Paper, viz:

$$I = \frac{C\,p}{\sqrt{(1 - C\,L\,p^2)^2 + C^2\,R^2\,p^2}} V_0,$$

he said the matter was greatly simplified by dividing both numerator and denominator by $C\,p$, thereby obtaining

$$I = \frac{V_0}{\sqrt{\left(\frac{1}{C\,p} - L\,p\right)^2 + R^2}}.$$

The numerator then became an *electromotive force*, and the denominator represented *ohms*, for since R was resistance in ohms $\left(\frac{1}{C\,p} - L\,p\right)$ must also be of the order ohms, otherwise they could not be added together. On Slip 17 Dr. Fleming had written the equation in practically the same way, but did not prove the equation there given. The proof of (31) was greatly simplified by taking the current as the given element instead of the pressure. For, assuming that $i = I \sin p\,t$ where I is the maximum value of the current, then in a circuit having resistance R and inductance L, in series with a condenser of capacity C, the pressure between the ends at any instance was given by

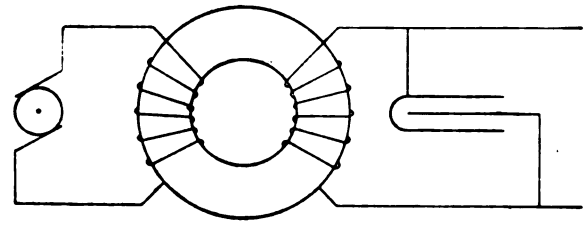
$$V = R\,i + L\frac{d\,i}{d\,t} + \frac{1}{C}\int i\,d\,t;$$

$$\therefore \quad = R\,I \sin p\,t + L\,p\,I \cos p\,t + \frac{1}{C}\int \sin p\,t\,d\,t;$$

$$\text{Hence } V = R\,I \sin p\,t + \left(L\,p - \frac{1}{C\,p}\right) I \cos p\,t.$$

The form of this expression showed that the phases of the two terms on the right hand side were in quadrature, hence the maximum values of V could be got by taking the square root of the sum of the squares of the coefficients, and equation 31 followed immediately. This method had also the advantage of introducing no differential equations of the second order, and was very convenient for teaching purposes. Referring to the so-called Ferranti effect, he inquired whether the pressure at the dynamo terminals was observed before the trunk mains were attached. He also took the opportunity of pointing out a mistake he had made in a diagram published in *The Electrician* on January 2, 1891. In this figure the connections were shown wrong, and hence gave the impression that a rise occurred in the part of the circuit representing the mains themselves. Although no rise had been observed, Mr. O. Heaviside had shown that under certain conditions such a rise would take place. He did not think Mr. Swinburne was correct in stating that he (Prof. Ayrton) had ever said there was a rise in the Deptford mains. What he did say was, that a voltmeter operated from the distributing mains at London read 100 volts, whilst a similar one actuated from the primary at Deptford read 80 volts; and this statement was now borne out by the figures published by Dr. Fleming.

Mr. EVERSHED thought neither Mr. Swinburne nor Prof. Ayrton had expressed the true feeling of the meeting towards Dr. Fleming for bringing forward such a valuable Paper. Although Mr. Swinburne had conceived the true explanation of why a rise of pressure should occur when the Ferranti trunk mains were connected to the transformers, he had not made himself clear, and his explanation was not complete, for the cause of the change in the ratio of transformation had not been given. The phenomena were, he thought, best considered separately. Taking the case of the general rise of pressure in both circuits by putting on a condenser, he pointed out that when the E.M.F. of the alternator was a maximum the condenser was fully charged, and no current passing into it, whereas the condenser current was a maximum when the E.M.F. was zero. Now, the E.M.F. of the alternator being zero when the armature coils are directly opposite the magnet poles, the condenser current attained its maximum at the instant when the coils were in a favourable position for influencing the fields. A little consideration, he said, showed that this current would strengthen the fields, and hence cause a greater E.M.F., and a rise would, therefore, be observed in both circuits.



To explain the change in the ratio of transformation he considered a 1 to 1 transformer having considerable magnetic leakage between the two coils. Just as was shown in the previous case, when a condenser was put across the secondary mains, the condenser current would be a maximum when the secondary E.M.F. was zero. But zero E.M.F. meant maximum induction in the iron, hence the condenser current being in step with the induction would increase the induction in the iron; but, owing to leakage, this increase would affect the E.M.F. of the secondary more than that of the primary, and hence change the ratio of transformation. It was, therefore, quite possible to neutralise the "drop" in transformers by putting on condensers, and had Mr. Ferranti designed his transformers to give a greater drop, he might have arranged so that when working on the trunk mains the "drop," instead of being converted into a rise, was exactly compensated. Referring to the method of writing equation (31) mentioned by Prof. Ayrton, he protested against the terms other than R being reckoned in ohms; for passing currents through ohms meant generation of heat, whereas no self-induction wasted energy. In his opinion the terms were of the nature of E.M.F., and ought to be called E.M.F.'s rather than resistances.

Prof. AYRTON asked Dr. Fleming to what cause he attributed the fact that the observed condenser currents given in Section 12 were considerably greater than those calculated. In some experiments made by Dr. Sumpner and himself on the same subject they had measured the current and calculated the capacity, and found the latter to agree very closely with that determined by ordinary ballistic methods.

Mr. SWINBURNE suggested that the increased capacity might be due to the "soaking in" which he had mentioned in his Paper on "Alternate Current Condensers," read before the Physical Society.

Mr. ADDENBROOKE said the soaking in of the charge might affect the capacity in a way similar to that in which the insulation resistance of a cable varied with the time the current was kept on. In giving the insulation resistance of any specimen it should be distinctly stated under what conditions the tests were made. Moreover, the resistance of a cable increased for a long time after it was manufactured, and almost any desired insulation resistance could be obtained by waiting long enough. In alternating current work the current was, he said, "on" for about $\frac{1}{100}$th of a second, and the resistance for such currents might be quite different to that found by steady-current tests. Information as to the properties of paper insulated cables, under various conditions, would be very valuable at the present time.

Mr. PREECE, replying to Prof. Ayrton's statement, that a coil having a time constant of 20 seconds could not be made, pointed out that Faraday's coil at the Royal Institution required two minutes for the current to attain its maximum value. A submarine cable when coiled in its tank had also an enormous self-induction, as was proved by a test made by Mr. Edison at the Telegraph Construction and Maintenance Company's Works, when he found that a telegraphic "dot" put in at one end of the cable came out 27in. long at the other.

Prof. AYRTON could not understand how self-induction could lengthen the dot, but capacity might do so.

THURSDAY, MAY 21ST.

Major CARDEW remarked that the condenser, on which the experiments mentioned in paragraph 12 of Dr. Fleming's Paper were made, had been constructed from imperfect plates, and since then a good condenser, kindly lent by Dr. Muirhead, had been carefully tested for capacity by the alternate current method. The capacity so found was in this case also greater than the capacity given by the makers. The discrepancy, he

Digitized by Google

thought, might be due to the fact that Dr. Muirhead determines his capacities by rapid charges and discharges, which, in consequence of absorption, would give a result too low, whereas in the alternate current method the absorption would have the effect of increasing the apparent capacity. Experiments had also been made by the voltmeter method, described by Prof. Ayrton and Dr. Sumpner, and Mr. Swinburne, on the power spent in a one-microfarad condenser when subjected to alternating pressures of 650 volts. The power found was five watts, and after a long continued run the condenser was not much heated.

Dr. SUMPNER pointed out that many of the formulæ given by Dr. Fleming could not be used practically without considerable reservation as to the value to be substituted for R and L in the expressions. Those obtained by bridge tests and ballistic methods would (if used) lead to conclusions which were entirely disproved by experiment. Years ago Maxwell showed that the mutual induction of two coils produced a result similar to that brought about by increasing the resistance of the primary and diminishing its self-induction. Since secondary circuits exist in all electrical apparatus in the shape of iron, copper, &c., not infinitely laminated, the changes in the so-called "constants" of the primary coil may be very important. The ordinary formula for the angle of lag between the E.M.F. and current in a coil being $\cos\theta = \frac{\text{Resistance}}{\text{Impedance}} = R\frac{A}{V}$ where A is the current and V the volts, then, since the watts given to the primary of a transformer with open secondary are watts $= V A \cos\theta$, and this by substitution becomes $V A . R\frac{A}{V} = A^2 R$, the power spent in the transformer would come out to be that wasted in heating the primary coil, if the value of R taken be that obtained by bridge tests. This, of course, was a totally wrong result, because the effect of hysteresis and Foucault currents was to virtually increase the resistance of the primary circuit. The results of bridge tests could not, therefore, be used in the customary manner. To get correct results it was also necessary to determine L by alternate-current methods, but as nearly all these methods involved the assumption that impedance $= \sqrt{R^2 + p^2 L^2}$, if the wrong resistance be taken, the resulting value of L would be inaccurate. Considering the Ferranti 150 horse-power transformer, and assuming that its exciting current was 5 amperes, he pointed out that, according to ordinary methods of reckoning, $L p$ would be about 2,000. This, although it only gave a time constant of about a second, whilst in the coil chosen by Dr. Fleming $\frac{L}{R} = 20$ seconds, was, nevertheless, about 100 times greater than that required to produce a lag of 80°. If, however, the value of R be taken as determined by the power spent on open secondary circuit, the ratio of inductance to resistance would only be about one one-thousandth of that possessed by Dr. Fleming's coil. The author, he said, had made no reference to Mr. Swinburne's views on the Ferranti effect, nor to the results published in a Paper read by Prof. Ayrton and himself before the Physical Society. The experiments given in Table I. (section 17), did not show whether any of the rise occurred in the dynamo as well as in the transformer. The same theory accounted for rises in both parts; but as Mr. Swinburne had pointed out, the primary circuit of a transformer could not act like a coil with self-induction, unless there was some magnetic leakage. In the experiments made at the Central Institution, it was found that, under certain conditions, about half the rise was due to the self-induction of the transformer and the other half to the dynamo; the proportions differed, however, with the ratio of transformation.

Mr. BLAKESLEY said that for some time he had considered the measurement of self-induction by alternate current methods to be a dangerous operation, particularly when there was iron in the field, for in that case a coefficient was hardly conceivable. In 1886, he tested the coefficients of a Gaulard and Gibb's transformer, which, because the primary and secondary were similar, and similarly situated, ought to have had a ratio of 1:1, really gave a ratio of 3:2. Speaking of the rise of pressure produced by capacity, he pointed out that he published an account of such a rise long before the Deptford station was commenced, and he was not at all surprised when he heard that such a rise occurred there.

Mr. A. SIEMENS, referring to the curve given in Fig. 6, said that more recent experiments, using a different type of transformer, showed that the ratio of transformation was independent of the capacity.

Prof. AYRTON inquired what was the difference in the two kinds of transformers used, and

Mr. SIEMENS replied that one was an open-circuit and the other a closed-circuit transformer.

Mr. SWINBURNE directed attention to the practical points to be attended to in coupling alternators in parallel on mains having capacity. Another important point he had recently observed was that by employing a motor in conjunction with an alternator, the effect of capacity could be neutralised, for weakening the fields of the motor caused it to act like a self-induction. By strengthening the fields of a motor it could be made to act like a capacity. Hence, even in transmitting power over long distances by alternate currents, an attendant at the receiving end could maintain the pressure at that end constant independent of the load by simply varying the strength of the fields of a motor working on the circuit.

Dr. FLEMING, in his reply, thanked Dr. Sumpner for calling attention to the parts he had omitted from the Paper, and said that some practical method of getting the inductance of a transformer at any load was greatly needed. He, Dr. Fleming, had hitherto failed to get a clear idea as to what Mr. Swinburne's views really were, but he thought that both the orthodox theory and the armature reaction view would be found wanting in some respects. A significant fact, however, was that with large machines of small inductance no rise was observed; whereas, when small machines of comparatively large inductance were used the rise was great. In laying out future stations, it would be quite safe to use concentric cables where alternators of small inductance could be coupled direct on the mains. Whilst agreeing with Prof. Ayrton's remarks about the faulty wording in paragraph 6, and on the simplification of formulæ suggested, he thought that the criticism concerning the coil with a time constant of 20 seconds which he (Dr. Fleming) had chosen, was unnecessary, since Mr. Preece had given an instance of a coil which required two minutes for the current to reach its maximum; and Mr. Bate had called his attention to the fact that the field magnets of an Edison "Jumbo" machine required nine seconds for the current to attain its maximum. The construction of a coil such as he had imagined was thus only a question of cash and of space, and was not an impossibility. Speaking of the formulæ given in his Paper, he pointed out that good condensers could be looked upon as having negative inductance equal to $\frac{1}{C p^2}$ and impedance $\frac{1}{C p}$. For leaky condensers the inductance was given by $\frac{C}{k^2 + C^2 p^2}$ where k is the conductance of the condenser. The resistance of such a condenser to alternating currents was represented by $\frac{k}{k^2 + C^2 p^2}$, and its impedance by $\frac{1}{(k^2 + C^2 p^2)^{\frac{1}{2}}}$. The denominator of the latter expression had, he said, been called the *admittance* of the condenser by Mr. Heaviside, and just as *impedance* had now come into general use, so *admittance* would be found necessary when high frequencies become more common. Referring to Major Cardew's experiments on condensers, he thought that the observed effects might be due to leakage, for a leak would cause the capacity to appear greater when tested by alternating currents, and less when direct currents were employed. He could not agree with Mr. Evershed about the quantity of $L p$ being of the nature electromotive force, for although it was not of the nature of resistance in the sense of being dissipative, yet its dimensions were those of resistance, and only those of E.M.F. when multiplied by current. On the subject of throwing machines in parallel, he pointed out that the procedure depended entirely on the nature of the machines and of the circuit, for the operations necessary to put the large Deptford machines in parallel on the mains were the reverse of those required when the small machines were used. There was, he thought, still considerable room for investigation to separate the rise due to transformers from that due to armature reactions; one great difficulty was experienced in getting the resistances and inductances of the machines or transformers. Dr. Sumpner, he said, had greatly overestimated the magnetising current of the Deptford transformers, for instead of being 5 amperes it was, he thought, only ·4 ampere.

The following is the authorised abstract of the discussion which followed the reading of Mr. W. H. Preece's Paper on "Some Points connected with Mains for Electric Lighting," and of Mr. R. E. Crompton's Paper on "The Most Economical Mode of Feeding a Low-Pressure Network."

DISCUSSION.

THURSDAY, MAY 14TH. (AUTHORISED ABSTRACT.)

Mr. SWINBURNE remarked that in 1889 he had discussed the subject of disturbances in telephones with reference to concentric cables earthed at one end. Many persons thought no trouble would arise from such a course. This, he believed, was a mistake, for the outside conductor being near earth had a considerable capacity relative thereto. If a large current, say, of 250 amperes, was passing, the pressure between the two ends of the outer conductor would be about 210 volts, and this would cause a considerable earth current to surge backward and forward between London and Deptford. The effect of these currents had, he believed, not yet been observed, but it would become noticeable when the load got heavy. Mr. Preece, he said, thought earthing the secondary of a transformer tended to lead the current into temptation, but as a matter of fact the temptation was diminished by earthing the middle of the secondary. If this be done, neither secondary main could differ by more than 50 volts from the earth potential, whereas if one end be earthed, or neither, the risk and danger were considerably increased.

The further discussion was adjourned.

THURSDAY, MAY 21ST.

Mr. ADDENBROOKE said that the object of Mr. Preece's Paper was to point out the economy of the high-pressure principle, whilst that of Mr. Crompton's was to impugn that principle. On examining the question as to the cost of high-pressure mains, he found that to give a 10 per cent. loss in 2,400 yards of feeder supplying 100 kilowatts at 2,000 volts, would require a 7/14 cable, and this, of best Silvertown make, would cost about £165 per mile. This would give the cost of cable about £400 instead of £1,200, as stated in Table I. The cost of the culvert or pipe was taken the same for both the high and low pressure feeders. This, he thought, was unfair to the high-pressure system, and the cost of the transformers and apparatus was also too high. Altogether, the cost of the high-pressure feeder ought to be put at about half that of the low-pressure one under the conditions there stated. These conditions were, however, not practical ones, for no A. T. engineer would allow a drop of 10 per cent. in so short a feeder; 2½ per cent. would be much more reasonable. Taking this drop, the cost of the cables would come to about £1,300, but the 7½ per cent. saving would mean an increased revenue of about £160 per annum.

Mr. JACKSON described the method of laying underground concentric mains as carried out by the Newcastle-upon-Tyne Electric Supply Company, and exhibited samples of the work. The system, he said, was a draw in and draw out one, using cast iron pipes and concentric cables for 2,000 volts pressure. The joints were made in junction boxes by bolting copper rings cast to thimbles, in which the ends of the cables were insulated to the tops of porcelain insulators. The same points served also as

Digitized by Google

connections for service lines, The advantages claimed were: simplicity and small cost, a six-mile circuit to feed 12,000 lamps with a variation of pressure never exceeding 6 per cent., having been laid at about £1,100 per mile. At the suggestion of the president Mr. Jackson promised to communicate further details in writing, for publication in the *Journal*.

Mr. KAPP said the case which Mr. Addenbrooke had made out for the A. T. system was not strong enough, for Mr. Crompton's calculations were vitiated by not taking the extra cost of plant into account. With a low-pressure feeder of 90 per cent. average efficiency about 30 per cent. more boiler, engine, and dynamo power would be required, as well as 30 per cent. more wages, &c., than for a high-pressure system. Mr. Crompton would thus have to lay down 30 per cent. more plant, and pay 30 per cent. more wages and interest for the privilege of using a low-pressure feeder.

Major-General WEBBER said Mr. Crompton wished them to believe that the A. T. people had now found that it would be necessary to use a low-pressure network, such as used in direct current distribution. This, he said, was by no means new, for Mr. Ferranti, as long ago as 1885, described a system like the one now mentioned by Mr. Crompton. Referring to Table II., he noticed that its author there admitted that 25 per cent. of the 2,400 yards of feeder would have to be laid in tubes. In practice, however, it was found that culverts could only be used for about a quarter of the total distance, and making this change would increase the cost of the low-pressure feeder by about £2,000; the interest would also be considerably augmented. Speaking of the 1 per cent. depreciation allowed on culverts and copper, as against 8 per cent. on cables, he said there was no admitted proof that the up-keep of one would be only one-eighth of the other. This point he (Major-Gen. Webber) had referred to in his Paper read last winter, but he was now sure that the figures 1 per cent. and 8 per cent. could not be admitted.

Sir W. THOMSON inquired what ratio the energy sold had to that generated in the various systems of distribution. In his opinion, the comparison would be favourable to the low-pressure system wherever it was practicable. In dealing with large conductors, both Mr. Preece and Mr. Crompton seemed to have ignored the fact that the conductivity was less for alternating currents than for direct ones. Conductors of 2 centimetres diameter offered 8 per cent. more resistance when the frequency was 80, whilst for 3 centimetres diameter the increase was 31 per cent. Mr. Preece's square inch section conductor would offer 25 per cent. more resistance to an alternating current of 80 periods per second, and at 100 periods the increase would be 30 per cent. As this was a matter of considerable importance in low-pressure networks he would suggest that all cables for currents greater than 200 amperes be made with jute instead of copper in the centre. On the whole, he thought it injudicious to rush to alternate currents for distribution purposes, and he himself rather inclined to continuous current distribution by feeders, as described by Edison. He was quite aware of the processes which had led to the A. T. system being usually preferred, and of the great advantages which in some cases could be realised by its use, but he believed that in future the direct system would predominate. The general idea in putting the generating station at a distance was to obtain cheaper coal, but he doubted whether more than 6d. per ton could be saved in this way. The possible use of condensation was another item, but so far as he was aware triple-expansion condensing engines had not come into use for lighting purposes. Rent of land was, however, an important consideration, as well as the necessity of diminishing vibration. Both these told in favour of the distant station, and, in his opinion, no other consideration ought to prevent engineers from putting their stations as near as possible to the consumers.

Mr. A. SIEMENS thought the principal object to be aimed at in designing stations was *simplicity*, and the design for a particular district must be guided largely by local circumstances. In his opinion the discussions on both Mr. Crompton's Papers had converged too much on high and low pressure. Speaking of cables he said that in addition to the theoretical conditions referred to by Sir W. Thomson, practical and financial points had also to be kept in view. In making concentric cables for the London Electric Supply Corporation, they had found that putting in a jute core increased the diameter of the cable, and added considerably to the cost. It was cheaper for them to put in extra copper to make up the conductivity. Referring to Mr. Crompton's estimate for the up-keep of mains, he concurred in Major-General Webber's protest against the 8 per cent. for insulated cables. As a matter of fact neither the cables put down in Berlin in 1881, or those in use at Bradford, had cost a farthing for up-keep since they were laid. In his opinion the up-keep of cables ought not to be put at a higher figure than that allowed for culverts.

Mr. SWINBURNE said the "skin effect" could be minimised, even in large conductors, by making them, say, in six smaller cables, stranded round an inactive centre.

Sir W. THOMSON pointed out that if each wire of such a cable was as much outside as any other wire, the full conductance would be obtained, but this condition was not fulfilled in cables as ordinarily constructed; and in conductors two or three centimetres in diameter, the conductivity for alternating currents is seriously diminished. With reference to the up keep of cables, he thought that, if properly constructed and laid, the up-keep should be practically *nil*.

Mr. A. E. MAYOR said that, by soaking the separate wires in an insulating medium before stranding, considerable resistance could be got between the strands; a light serving of cotton did not seriously increase the diameter of the cable. In this way he thought Mr. Preece's square inch section could be obtained without much diminution in conductivity for alternating currents. He characterised Mr. Crompton's estimate of £1,300 for 2,400 yards of concentric cable as absurd, and he assured Mr. Preece that great attention was being given to the construction of mains. He was also of opinion that rubber would be superseded by cheaper dielectrics. On the subject of feeding a network, he had no doubt but that high-pressure cables would be much cheaper than low-pressure ones.

Mr. PREECE, in reply to Sir W. Thomson, said that in one alternate current system with which he was acquainted the coal burnt per unit sold was 17lb., whilst per unit generated it was 8lb. In Rome, however, these numbers were 10lb. and 8½lb. respectively. This satisfactory result he attributed to the system of "banking" the transformers. Of direct current systems, he said that Mr. Crompton's statements were not corroborated by the Company's returns, for whilst he (Mr. Crompton) gave 7 to 8lb. as the consumption per unit generated, and 8 to 9lb. per unit sold, a Director informed him (Mr. Preece) that they did not get paid for two-thirds of what they generated. He hoped that before long it would be usual to get an indicated horse-power hour for 2 to 2½lb. of coal, and that 6 or 7lb. per unit sold would suffice. Referring to the square inch section of copper mentioned in his Paper, he said this was taken merely as an illustration. In practice, none of the mains need ever exceed a quarter of a square inch in area, and, as shown in his Paper before the British Association, the reduced conductance of such sizes for ordinary frequencies was not important. Sir W. Thomson, he remarked, had said a great deal in favour of low-pressure systems with numerous stations, but in so doing he had, apparently, overlooked the fact that working expenses were greatly increased by this duplication of stations. In designing the Bristol scheme, two stations were found to be much more expensive than one, and it was for this reason, and on account of its greater "simplicity," that the alternate current system with one station had been chosen. The three-wire system, he said, was not financially possible at distances greater than half a mile; while for five wires, the limiting distance was about a mile.

Mr. Crompton, not being present, did not reply.

A PHOTOGRAPHIC STUDY OF THE ELECTRIC ARC.*

BY EDWARD L. NICHOLS.

The arc lamp, fed by alternating currents, invariably hums and sings. The note, which is not to be mistaken for the hissing which we hear from continuous current lamps that are burning under improper conditions, possesses a definite pitch, determined by the rate of alternation of the dynamo. That the note is not due to the mechanism of the lamp itself is readily shown. The Jablochkoff candle, which is devoid of all mechanism, sings as merrily as the lamp with solenoid regulator; any form of hand-lamp will do the same. I do not remember having seen any definite statement concerning the source of this humming noise, nor any satisfactory discussion of the question. My attention was first brought to the very obvious explanation of the phenomenon by the study of certain curves of electromotive force, obtained by Messrs. Archbold and Teeple, in the course of an investigation of the alternating discharge between a ball and point. Shortly after this curve had been obtained, the curves of Messrs. Tobey and Walbridge, illustrating the performance of the Stanley arc lighting dynamo, appeared.

After studying these curves it seemed to me unquestionable that the humming of the alternating arc is due to the rapid periodic extinction and re-establishment of the discharge, the effect being similar to that observed in singing flames. When, some months later, opportunity was found of viewing the image of the arc of an alternating current lamp in the revolving mirror, I was prepared to witness the extinction of the arc during a definite part of each alternation. I do not know whether any member of the Institute has tried this simple experiment. I have seen no description of it anywhere, although Wiedemann mentions the application of the revolving mirror to the study of the continuous current arc†, and Joubert‡ (1880) makes brief mention of a very ingenious application of the plenakistiscope to the study of the changes to which the alternating arc is subject, during each period. When such a mirror, mounted upon a vertical axis, is set up at a convenient distance from the lamp, the images of the white-hot tips of the upper and lower carbons are drawn out by the revolution of the mirror into uniform, parallel bands, extending quite across the field of view. The intervening narrow strip, much darker, is the image of the arc itself. This region, however, is not uniform, It consists of alternate patches of purple and black, which mark the intervals during which the arc exists and is extinct.

Mr. McMynn's first step in the investigation which it is my purpose to discuss in this Paper, was to photograph the arc under conditions which would bring out this phenomenon. A camera with long bellows was set up near the lamp, the distances from plate to lens and from lens to lamp being such as to give a somewhat enlarged image of the arc. In the focal plane an opaque screen was mounted, which contained an opening just large enough to receive the image of the carbon points. The apparatus having been adjusted, a sensitive plate was driven past the aperture at high speed. The photographic image differed from that observed in the revolving mirror chiefly in the relative brightness of the arc

* Based upon experiments made by Mr. J. C. McMynn. Abstract of a Paper read at the general meeting of the American Institute of Electrical Engineers, New York, May 20, 1891.

Digitized by Google

proper, and of the incandescent carbon of the points. To the eye, the latter is the dominant feature; whereas the *actinic* image of the arc far exceeded in intensity that of the carbons.

These photographs establish the intermittent character of the alternating arc beyond question. They also exhibit in a new

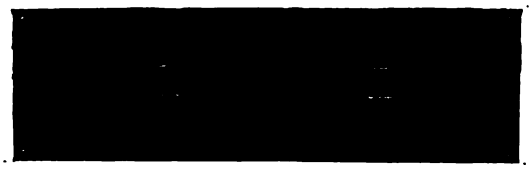

FIG. 1.—Alternating Arc. Long Arc (58 volts.) (Movement of Plate horizontal.)

light many interesting properties of the arc, some of which are already well known, while others have not been noted. Of the many negatives already obtained, a few characteristic forms are given in the accompanying plates.

FIG. 2.—Alternating Arc, showing oscillations due to Earth's field. (Movement of Plate vertical.)

Fig. 1 is an enlargement of one of the first negatives taken, with plates moving in a horizontal direction, at right angles with the axis of the carbons of the lamp. The speed of the plate was moderate, the size of the image smaller than the arc itself. The

FIG. 3.—Alternating Arc between Cylindrical Carbons. Arc viewed from West (Movement of Plate vertical.)

plate contains but little detail. The carbons do not appear at all in the photograph, which shows little besides the periodic interruption of the arc. In later negatives the size of the image was greatly increased and the plate was driven much more rapidly through the field. In many instances two or more successive exposures were made upon the same negative. Inspection shows that the greatest intensity resides neither in the arc itself nor on the incandescent carbons, but in the narrow region just at the ends of the arc. In this region, which, doubtless, is that where the so-called "contac-resistance" of the arc occurs, the illumination is sometimes intert mittent, as in Fig. 1; sometimes nearly uniform. The relative width of the intervals of darkness and of light is also seen to vary greatly under conditions not yet determined.

Figs. 2, 3, 4, and 5 were obtained by driving the plate vertically through the field, parallel to the carbons. An unlooked-for feature of all these plates was the oscillation of the arc from right to left in synchronism with the alternation period. Mr. McMynn suspected this vibration to be due to the action of the earth's magnetic field.* He was able to verify his view by comparing photographs made with the camera placed with its optical axis in the meridian with others in which the arc was viewed from the east or west. The disturbance was most marked in the former position and disappeared almost entirely from negatives taken in the latter. This point is well illustrated by Figs. 2 and 3, which show the image obtained from the north and from the east. The lamp in this case was supplied with cylindrical carbons. All the other photographs represent the arc between flat carbons. In a strong field, produced by placing the arc nearly between the poles of a horse-shoe magnet, the lines of force being

FIG. 4.—Alternating Arc, showing Oscillations in a stronger Field than in Fig. 2. (Movement of Plate vertical.)

perpendicular to the axis of the lamp and parallel to that of the camera, the vibratory effect was much increased (Figs. 4 and 5).

In this brief discussion I have left untouched many points which will suggest themselves to those who study Mr. McMynn's photographs. The interpretation of many of the features of these plates

FIG. 5.—Alternating Arc in a strong Magnetic Field. (Movement of Plate vertical.)

is at present rather obscure, but it is hoped that experiments now in progress will add something to our present knowledge of the phenomena connected with the alternating electric arc.

* It should be noted that Casselmann, as long ago as 1844, described the deflecting action of the earth's field upon the continuous current arc. (See *Poggendorff's Annalen*, 63, p. 588.)

PHYSICAL SOCIETY.

At the meeting of this society, on May 22nd, Prof. PERRY, F.R.S., showed a new form of steam engine indicator (see Figs. 1 and 2.) A galvanometer mirror is fixed excentrically to a steel disc forming one side of a chamber communicating with the cylinder. The pressure of the steam bulges out the disc and causes the mirror to deflect a ray of light thrown on it in the ordinary way. A rotation at right angles to the former is imparted by the movement of the piston rod. The ray of light traces out the diagram on a screen suitably placed, and the complete figure is continuously visible owing to the persistence of impressions. This indicator possesses advantages over other forms, in being free from errors due to friction, or oscillations of the

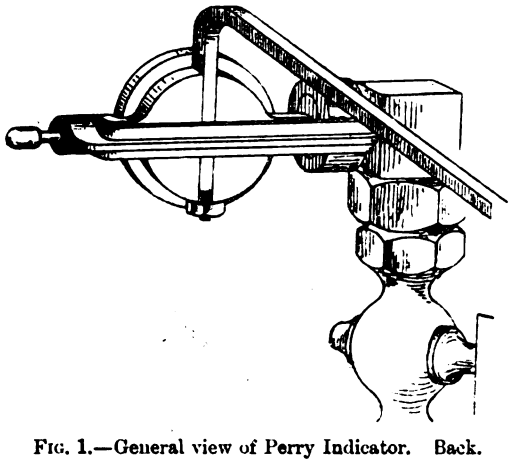

FIG. 1.—General view of Perry Indicator. Back.

springs and the alteration of their elasticity due to temperature changes. The errors of ordinary indicators are considerable at high speeds, owing to the ripples introduced into the indicator diagram. If the natural period of the spring is one-twentieth of the time of a revolution, the diagram is fairly free from ripples, but if it is as much as one-tenth no amount of friction in the indicator will prevent ripples forming. In the new indicator the

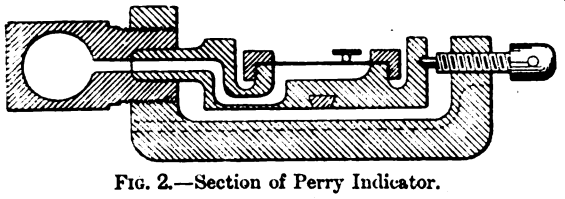

FIG. 2.—Section of Perry Indicator.

natural period of the disc can be made very short. The steel discs are easily movable, and can be proportioned to suit different pressures and speeds. For experimental and teaching purposes it is advantageous to see at once the alterations in the diagram caused by changes of load, pressure, &c. Several diagrams were exhibited to the meeting.

DISCUSSION.

In reply to Prof. Carus Wilson, Prof. PERRY stated that the deflection was proportional to the pressure in the cylinder within the limits for which any particular disc was intended.

Mr. ADDENBROOKE thought the instrument an important improvement on its predecessors, and considered it would prove of great service to electrical engineers.

Mr. SWINBURNE, said a peculiar merit of the indicator was that it could be permanently attached to an engine, like an ordinary pressure-gauge. He suggested the use of a small telescope instead of the ray method.

Prof. AYRTON thought that the instrument could be modified so as to be useful for analysing the shape of the curves representing alternating currents.

"Blakesley Method of Measuring Power in Transformers,"

BY PROF. PERRY, F.R.S.

This Paper referred to the supposed error in Mr. Blakesley's formula, due to the fact that transformers show magnetic leakage. The proofs of the formula hitherto given have been obtained by treating the equations in the manner first adopted by Dr. Hopkinson. On this system the reactions of the primary and secondary currents are represented by the equations

$$V = R_1 C_1 + P \frac{dN}{dt} \qquad 0 = R_2 C_2 + S \frac{dN}{dt},$$

where P and N are respectively the turns on the primary and secondary coils, and N is the magnetic flux between the coils. Here it is assumed that there is no magnetic leakage, and the author thinks that on this account the method is inferior to the original method of Maxwell, in which the induced electromotive forces are expressed in terms of co-efficients of self and mutual induction. On the assumption that there are no eddy currents Maxwell's equations are

$$V = R_1 C_1 + L_1 \dot{C}_1 + M \dot{C}_2 ; \qquad 0 = R_2 C_2 + M \dot{C}_1 + L_2 \dot{C}_2,$$

in which although L_1 M and L_2 may not be constant, it may be assumed that they are respectively proportional to P^2, PS, and S^2, if there is no magnetic leakage, and if the amount of magnetic leakage bears a constant proportion to the whole flux, the three quantities may still be assumed proportional to each other although M^2 is less than $L_1 L_2$. From these equations we obtain

$$V C = R_1 C_1^2 - R_2 \frac{M}{L_2} C_1 C_2 + \frac{L_1 L_2 - M}{L_2} C_1 \dot{C}_1.$$

Hopkinson puts down the last term as zero, but, owing to the very rapid rate at which C_1 changes, the last term is very important, even though M may be but a small percentage less than $\sqrt{L_1 L_2}$. On integrating this equation the first two terms on the right-hand side yield Blakesley's formula, and the last term vanishes in the integral because, however great the magnetic leakage may be,

$$\int C_1 \dot{C}_1 \, dt = 0,$$

when taken over a period, because the functions are periodic. Mr. Blakesley's formula thus appears to hold whatever the magnetic leakage. The Paper contains several tables of calculations showing the effect of magnetic leakage on the value of the terms in the equation.

DISCUSSION.

Mr. BLAKESLEY said he doubted the correctness of the assumption that the value of M was the same in the two equations, and thought that the result arrived at must be incorrect.

Dr. SUMPNER did not doubt that if the coefficients could be considered constant the formula was true, whatever the leakage ; but he did not consider that the action of transformers justified such an assumption. If the formula were true, it would also hold if there were eddy currents, as these would merely produce the effect of additional secondary coils. He had analysed Blakesley's method by using a modification of the Hopkinson equations, and had shown that the power, as estimated by Blakesley's formula, had to be lessened by the fraction represented by the expression—

$$X = \frac{\int x \dot{A}_p \int A_s \, dt \, dt}{\epsilon + \int A_p A_s \, dt},$$

Where A_p and A_s are the instantaneous values of the primary and secondary currents, and x is such that $N_p = N_s (1 + x)$ where N_p and N_s are the fluxes of magnetism at the same instant, through the primary and secondary coils respectively, and ϵ is a negligibly small quantity compared with the rest of the denominator. In obtaining this factor no assumptions whatever had been made, and it was easy to see that, if A_p and A_s could be assumed sine functions, and x a constant, the value of the factor X became x simply. In only one case did X reduce to zero, and that was when x was a sine function of the same period as A_p and A_s. He believed that in actual transformers x was approximately constant.

Mr. SWINBURNE pointed out that the split dynamometer was merely a wattmeter, and stated that he had transformers which, owing to magnetic leakage, would indicate an efficiency of over 100 per cent. if tested by Blakesley's method. If this method gives an efficiency of 95 per cent., and leakage causes a drop of 2 per cent. in E.M.F., the real efficiency is only about 94 per cent. He thought that the assumption that the currents followed a sine law was equivalent to supposing that there was no loss in hysteresis.

Prof. AYRTON said that no one would be more glad than himself to find that Mr. Blakesley's method was accurate, but he could not agree with Prof. Perry that Dr. Hopkinson was wrong in abandoning the academical method of Maxwell.

Prof. PERRY replied to the various points raised in the discussion. A paper on "Current and Potential Difference Analogies in the Methods of Measuring Power," by Prof. W. E. Ayrton and Dr. Sumpner, was postponed.

ON THE INFLUENCE OF TEMPERATURE AND MOLECULAR STATE ON THE BEHAVIOUR OF BISMUTH IN A MAGNETIC FIELD.*

BY P. DRUDE AND W. NERNST.

The two questions considered by the authors are the following : What is the influence of temperature on (1) the Hall effect in a bismuth disc ·5cm. thick by a magnetic field ; (2) on the increase (first observed by Righi) in the resistance of a bismuth rod traversed by an electric current in a magnetic field.

For solving the former question, plates of bismuth, one square and the other circular (the latter being placed in a glass vessel) were used. At points 90deg. apart on the circumference four

* *Wied. Ann.*, Vol. 42.

Digitized by Google

platinum wires were fused in. The pair lying on one diameter carried the primary current, whilst the other two were connected to a galvanometer in order to show the Hall effect. The plates were enclosed in a narrow sheet iron box suspended between the poles of a powerful electro-magnet, and were heated with steam.

If e represents the E.M.F. of the Hall current referred to equal primary currents and taken as unity at the original temperature, with the square plate the following values were obtained :—

t	.....	20°	.....	254°	.....	23°	
e	.....	1·000	.....	0·418	.....	1·005	

and with the round plate melted into the glass vessel, the values :—

t	.....	14°	.....	243°	.....	100°	..... 14°
e	.....	1·00	.....	0·23	.....	1·23	..... 1·16

When the bismuth in the glass vessel was in the fluid state, the E.M.F. was 60 to 100 times less than when at the temperature of the room. The figures further show that the bismuth on cooling does not return entirely to its original state. In the interval between 243° and 310°, during which occurs the melting point of bismuth, the decrease in e extends considerably lower than is shown in the above values.

In order to decide the second question bismuth was melted in a thin capillary glass tube, and at each end two platinum wires were provided. One pair served to conduct the primary current, whilst the other led to a galvanometer. The deflection shown by the latter when the primary circuit was closed was, therefore, proportional to the resistance of the bismuth. The results obtained are given below, where r represents the resistancein Siemens units at a temperature t and δr, the increase in resistance due to the formation of the magnetic field at this temperature :—

t	r	δr	t	r	δr
16°	0·250	21·9 per cent.	290°	0·117	0·41 per cent.
100°	0·227	8 ,,	35°	0·207	15·1 ,,
223°	0·250	0·96 ,,	18°	0·208	18·6 ,,

The non-return on cooling to the original condition may be due to the bismuth having melted partly away from one of the platinum wires. In the neighbourhood of the melting point the influence of the magnetic field is clearly very slight, which corresponds to the results obtained on the first question.

The Hall phenomenon was also investigated with a plate of antimony, the influence of temperature being in this case much less noticeable. Mercury does not exhibit the Hall effect, but its resistance increases by about 0·2 per cent., when it is traversed by an electric current in a magnetic field.

PARLIAMENTARY INTELLIGENCE.

THE ELECTRIC LIGHT AT KILLARNEY.

Among the private bills which were down for consideration by the House of Commons on the 28th ult., was the Electric Lighting Provisional Order (No. 7) Bill, which came up for second reading, and which gave rise to some discussion.

On the motion that the Bill be read a second time,

Mr. ARTHUR O'CONNOR said he had been asked to oppose it on behalf of Mr. Sheehan, M.P., who was the Chairman of the Killarney Town Commissioners, and who was too ill to be present himself. He had, he said, no objection to the Bill so far as it related to the English towns included within its scope, but when it came to Killarney it was a different matter. All the other places were large and populous centres, whereas Killarney was not a town at all, but was a mere village. By the scheme which related to Killarney they were asked to give an important concession to a private individual, named Mr. Leahy, who was to enjoy the monopoly of supplying the electric light to this particular town for a period of 28 years. What he had to point out in connection with this matter was that Mr. Leahy was not a member of the Killarney community himself, but came from outside the district altogether. The Town Commissioners and the people of Killarney very properly contended that if they were to have the electric light the necessary powers should be placed in the hands of the Town Commissioners, who were the local authorities responsible for the government of the town. He might be told that the Town Commissioners had already held a meeting at which Mr. Leahy's scheme was fully considered, and that, after a careful consideration of the matter, the meeting sanctioned the scheme, which now came before the House with their approval. His reply to that was that the meeting in question was altogether irregular, that it was not properly constituted, and that, therefore, it had no power either to approve of or reject the scheme. He was informed that Mr. Jeremiah Sheehan, although he was the Chairman of the Town Commissioners, and although he was residing in Killarney at the time the meeting was held, received no intimation whatever that such a meeting was to take place ; and several other commissioners were in precisely the same position. It was on these grounds that he opposed the second reading of the Bill.

Sir MICHAEL HICKS-BEACH, on behalf of the Board of Trade, said that Killarney was not like an ordinary Irish agricultural town. It was a place which was much resorted to by visitors from all parts, and it had been deemed advisable to put forward a scheme for lighting it by the electric light. This scheme had been before the Town Commissioners, who had approved of it, and this was the first he had heard of any supposed irregularity in the calling of that meeting. The application for powers to supply the electric light was opposed by Lord Kenmare and certain other persons who were lessees of the Gas Company ; and, with all respect to the hon. gentleman who had raised this question, he must say that he thought the real opposition to the Provisional Order came, not from the inhabitants of Killarney, but from the Gas Company. The Town Commissioners originally intended to apply for a Provisional Order ; but, having further considered the subject, they withdrew their application and entered into an agreement with Mr. Leahy that he should pay them the expenses which they had incurred, and that they would then assent to his obtaining a Provisional Order, with certain amendments, reducing the maximum price of the electric light, and the number of years during which Mr. Leahy was to have the monopoly. The terms agreed upon were distinctly favourable to the Commissioners. So far from there being any general objection on the part of the residents of Killarney, there had been no petition against the scheme since the arrangement he had indicated was entered into. Under these circumstances he asked the House to read the Bill a second time, and then, if any further inquiry was deemed advisable, he should not have the smallest objection to referring so much of the Bill as related to the Killarney scheme to a Select Committee,

Mr. O'CONNOR was afraid any inquiry before a Select Committee would result in a heavy expenditure, so that the offer was scarcely one that he could accept. Would the right hon. gentleman allow the matter to stand over, to enable communication to be made with the Board of Trade from Killarney ?

Sir M. HICKS-BEACH did not see what could be gained by such a course. If the Bill was read a second time now there would be ample time to make any necessary inquiries before the further stages of the Bill were taken.

The Bill was then read a second time.

LEGAL INTELLIGENCE.

Hampton and Sons v. The London Electric Supply Corporation.

In the Queen's Bench Division of the High Court of Justice, on Thursday last week, the case of Hampton and Sons *v.* London Electric Supply Corporation (Limited) came before the Lord Chief Justice of England and a special jury. This was an action brought by the plaintiffs, upholsterers, &c., carrying on business in Pall Mall East, against defendants to recover £3,000 damages in respect of an alleged breach of contract. The defendants denied that there was any contract between them and the plaintiffs. Mr. Jelf, Q.C., and Mr. Lee Roberts appeared for the plaintiffs, while Mr. Moulton, Q.C., and Mr. Pyke represented the defendants.

Mr. JELF, in opening the case for the plaintiffs, said that in 1888 they extended their premises by erecting new buildings. They were anxious to have their premises fitted with the electric light, and they accordingly put themselves into communication with the defendants, with the result that the defendants agreed to give them a continuous and regular supply of electric current to the extent of 600 lights. In order to make their premises suitable for an installation, the plaintiffs expended considerable sums of money. Originally it was arranged that the plaintiffs should have the supply by October 1, 1888, but the period for carrying out the necessary works was extended by mutual consent to November 27th. The defendants, however, failed to give the plaintiffs the supply of electric current, and the result was that they sustained a considerable loss. The defendants had agreed to supply the plaintiffs with the current at 12s. per light per annum, but in consequence of the breach of contract the plaintiffs had to obtain a supply of electric current from another company, at a charge of 25s. per light. The plaintiffs were without electric light from November until March, and in order to light up their new premises they had to use oil lamps, which seriously affected their trade. He (the learned counsel) submitted that there had been a clear breach of contract, and that the plaintiffs were entitled to substantial damages.

Mr. HAMPTON, one of the plaintiffs, was called, and bore out the opening statement of counsel. He added that the failure of the defendants to supply his firm's premises with the electric current had a serious effect upon their business. The takings of the firm from December, 1887, to March, 1888, inclusive, amounted to £55,998, but during the same period of the following year they fell to £36,041.

Mr. CLAREMONT, formerly engineer in the employment of the defendants, Mr. J. E. GORDON, of the Metropolitan Electric Supply Company (Limited), and Mr. R. S. ERSKINE, of the Kensington and Knightsbridge Electric Lighting Company, also gave evidence in support of the plaintiffs' case. In cross-examination, Mr. Gordon admitted that 25s. per lamp per year was a fair price.

Mr. MOULTON, in opening the case for the defendants, contended that the correspondence between the plaintiffs and his clients did not amount to a contract. The defendants offered to supply the plaintiffs with the electric current at the rate of 7½d. per unit, and they had always considered that such an offer was determinable by the customer simply giving notice that he desired to discontinue the supply. The customer was not compelled to use the current ; it was connected to his premises, and if he used it he was charged according to what he used. That being so, it was absurd for the plaintiffs to contend that the defendants were liable for every conceivable item of damage which might arise from an accident to the supply. In the winter of 1888 there was a long period of fog and darkness, and consequently there was a great strain upon the defendants'

Digitized by Google

plant. Unfortunately this strain ended in the breakdown of their principal machine. The defendants had to restrict the supply of electric current to their customers and to decline to accept any new applicants. They were also compelled to withdraw the offer to supply the plaintiffs with the electric light. Instead of being in a position to take the electric current in November, 1888, the plaintiffs' new buildings were not properly fitted until February 15th, and they had a supply of electric current by March 11th. The defendants, while denying liability, had paid £75 into Court to meet any damage which the plaintiffs might have sustained.

Mr. CUNDELL, electrical engineer, stated that he was employed by the plaintiffs to superintend the fitting up of their premises for the electric light. Messrs. Crompton and Co. fixed the necessary wires, &c. The whole of the work was not completed until February, 1889.

Mr. WILSON, an electrical engineer, formerly in the employ of the defendants, and Mr. R. S. BAIN, chief accountant to the defendants, also gave evidence in support of defendants' case.

The learned counsel having addressed the jury on behalf of their respective clients,

His LORDSHIP summed up the whole case, and asked the jury whether there was any document in the case which could be called a contract, and, if so, whether it had been broken. In the event of their answering these questions in the affirmative, they would also have to say what damages the plaintiffs had sustained. He reserved to himself the power of subsequently determining whether there was a contract in point of law.

The jury found that there was a contract in the terms of the form of application, and that there had been a breach, and they assessed the damages at £250.

Mr. Lee Roberts on Friday morning applied to his Lordship to enter judgment for the plaintiffs in accordance with the findings of the jury.

The LORD CHIEF JUSTICE said he was unable to do so, as he could not see any evidence of a contract. Judgment would therefore be entered for the defendants with costs. A stay of execution would be granted with a view to an appeal.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May* 16, 1891.

The Portelectric System.—The New England Portelectric Company has just issued its annual report. The Portelectric system depends for its motive power on the attraction of solenoids distributed along the track for a cigar-shaped iron car. It is intended principally for automatically carrying mail and express matter at high speed over considerable distances. Prof. A. E. Dolbear is the electrician of the Company, and in addition the system has been thoroughly examined by Mr. F. L. Pope, a well-known electrical engineer in New York. An experimental track, oval in shape, and about 2,800ft. in total length, was laid out. The grades and curves were somewhat severe, and hindered thoroughly successful experiments. At the time of Mr. Pope's inspection the maximum speed attainable with the apparatus, as then arranged, was less than 35 miles an hour, but he expressed the opinion that this figure can be very much increased by using a better track, perhaps even rising so high as 150 miles an hour, although this latter figure seems purely hypothetical. The amount of wire required for solenoids per mile is nearly 20,000lbs., and in most of the experiments the flashing at the switches of each solenoid was most formidable. The passage of the car has been described by some observers as resembling more than anything else the fiery train of a rocket. Mr. Pope's suggestion for remedying this is the momentary short circuiting of each coil, and, although this would at the same time short-circuit the dynamo, it is perhaps the best way out of the difficulty. Altogether the results thus far obtained have not been particularly flattering to the system.

May 23, 1891.

Annual Meeting of the American Institute of Electrical Engineers.—With every year the annual meeting of the representative electrical organisation of this country grows in interest and importance. Last May the experiment was tried, for the first time, of holding it outside of New York City, and the Boston meeting will long be remembered by those who had the good fortune to attend it. This year the meeting was held as usual at the headquarters of the Institute, No. 12, West Thirty-first-street, New York, and was an unqualified success both as regards attendance and the character of the Papers presented. On Tuesday evening, May 19th, the opening meeting of the session was held, and was confined strictly to elections and business matters. Alexander Graham Bell was elected president for the ensuing year in place of Prof. William A. Anthony, whose term expired. This selection of the presiding officer met with the most cordial approval of the members. The vice-presidents elected were Mr. T. D. Lockwood, well known from his long and intimate connection with the telephone interests; Mr. O. T. Crosby, head of the railway department of the Thomson-Houston Company; Mr. Carl Hering, and Mr. W. J. Hammer. After the election of officers the formal reports of the secretary and treasurer were laid before the meeting and accepted, and a small amount of routine business was transacted; and an adjournment was then taken until Wednesday morning, when the first of the regular sessions should begin.

It was 10 o'clock the next morning when the electricians began to assemble around the headquarters, and 125 names were soon upon the records, more than 100 of them being members of the Institute. A little before 11 o'clock the meeting was called to order, and the first Paper was the interesting account of a stationary motor design by Prof. F. B. Crocker. This was a very neat and finished exposition of the principles of motor construction, especially as exemplified by the admirable series of machines designed by the author and his colleague, Dr. S. S. Wheeler. As might have been anticipated, the discussion brought out very many points of interest. The designing of the motor, apart from the dynamo, is a subject that has not been very freely treated in electrical literature, and consequently a number of the gentlemen present drew upon the stores of their practical experience for the edification of their fellow members. In fact, so instructive was the discussion that it prolonged itself until nearly one o'clock, when the other Paper put down for the morning was transferred to the afternoon. In the afternoon the first Paper brought up was Prof. E. L. Nichols's description of a very instructive series of experiments on the electric arc carried on by means of photography. After a brief discussion, in which Prof. Elihu Thomson was the principal speaker, Mr. Carl Hering read a Paper on a graphical method of calculating wiring that, like the previous Paper, led to a discussion of more interest than length, and in which Dr. F. A. C. Perrine showed another beautiful graphical method for accomplishing the same end. Dr. Perrine then went on to read a very clever and exhaustive account of the practical phases of electrical welding, as it had been tested in the great Roebling Factory, of which the author was the electrician. This Paper occasioned a somewhat lengthy discussion, in which Prof. Thomson took a prominent part, giving some interesting results of his own experience and a description of recent methods. Mr. F. J. Sprague's Paper on the rapid transit problem in New York was postponed until the morning. The evening session of Wednesday was a unique experimental lecture by Mr. Nikola Tesla, giving a series of the remarkably beautiful experiments with alternating currents of high frequency which he has carried on during the past year. Some account of this remarkable work was recently given in the *Electrical World*,* and the experiments shown were in part those described in that preliminary Paper. Mr. Tesla opened his lecture with a very suggestive general discussion of some of the phases of electrical theory that had led him into this particular field of research. The characteristic of the forces which he had turned to account in his investigations was the frequency of alternations enormously greater than had ever hitherto been used. Twenty thousand per second was reached during some portions of the experiments. Some very striking effects of high frequency sparks from induction coils were shown, magnificent brush discharges, the effect of adding capacity to the circuit, and of the increasing density at one of the electrodes. The most striking results, however, were the brilliant illumination of incandescent lamps and Geissler tubes at considerable distances from the induction coils, and the very extraordinary transference of energy through the glass walls of an incandescent lamp at short distances. These high frequency discharges from an inductorium do not pierce a dielectric in the ordinary sense of the word, but seem to stream through it even more freely than through the air. The attendance at this lecture was very large, and Mr. Tesla

* Reprinted in abstract in *The Electrician* of March 6, 1891, Vol. XXVI.

Digitized by Google

held his audience as it were spell-bound from half-past eight until nearly midnight.

Thursday morning Mr. F. J. Sprague's Paper on rapid transit in New York was read, and proved to be a most masterly discussion of the present situation and some of the general possibilities in the way of rapid transit. No attempt was made to describe any particular ideal equipment. During the discussion an exceedingly interesting brief address was made by Prof. George Forbes, giving some account of the success that has been attained in the City and South London Railway. Before the formal meeting the members of the Institute had spent some time in going through the Crocker-Wheeler motor factory, which was thrown open for their inspection, and the hour for adjournment arrived before any further Papers had been read. Early in the afternoon the remaining Papers were taken up. These included the description of a new device for measuring alternating-current potential, by Mr. Geo. S. Moler; the study of the variation of electromotive force in arc light dynamos, by Mr. M. E. Thompson, of Cornell University; and finally a group of three Papers that provoked most animated and vigorous discussion. One of these was by Mr. G. W. Walker, of New York, on electric meters. Mr. Walker is the inventor of a very beautiful and accurate photographic meter, and took up the cudgels for photographic and other integrating meters as against the mechanically registering type. His remarks on the Thomson wattmeter were somewhat severe, as he called special attention to the fondness of that instrument for continuing its rotations in one direction or the other when no electricity is being consumed, a phenomenon due to a stray field from the coils that are always left in circuit. Prof. Elihu Thomson and Mr. Edward Weston took an active part in the discussion at once, and some exceedingly instructive and edifying suggestions were the outcome of the triangular duel that ensued. Then came Dr. W. H. Wahl's discussion of the aluminium problem, which was calculated to arouse the advocates of electrical processes for extracting this metal, inasmuch as the author championed the purely chemical methods. The aluminium men were out in force, and comments were, to say the least, active. The concluding Paper of the session was read by Mr. Oberlin Smith, who endeavoured to persuade the assembly that aluminium should be called "alium" in the interest of those who are too lazy to speak five syllables. The suggestion was met with, perhaps, the most vigorous disapprobation ever visited on a Paper before the American Institution of Electrical Engineers, and it is not at all likely that the topic will be discussed further.

In the evening the Electric Club extended the privileges of the club house to the engineers, and a very pleasant reception occupied the evening. The entertainment committee of the Electric Club arranged for a loan exhibition of early electrical books, apparatus and models, of special and unusual interest, including some very rare specimens both of electrical literature and electrical apparatus. With this reception closed what on the whole, may be said to be the most successful meeting the Institute has ever enjoyed.

PARIS NOTES.

(FROM OUR OWN CORRESPONDENT.)

PARIS, *June* 2, 1891.

The electricity meter competition organised by the Paris Municipality terminated on Saturday last by the publication of the prize list. The Aron and Thomson-Houston meters have obtained the two first prizes of 5,000fr. each; these instruments, available alike for continuous and alternating current circuits, having been deemed by the Comtmittee of Experts to fulfil all the conditions laid down. M. Frager has obtained two prizes of 1,000fr., one for his continuous-current and one for his alternate-current meter; while M. Marès' ingenious continuous current meter has also been awarded a prize of 1,000fr. M. E. Hospitalier will shortly publish a full report of the exhaustive tests carried out.*

The Avenue Trudaine central station of the Compagnie Continentale Edison is now complete, and will shortly be formally inaugurated. The plant comprises four Wehyer and Richemond 300 H.P. engines, each coupled direct to a 300 H.P. double armature 8-pole Edison dynamo. These machines are very similar to some which have lately come into use in the United States (see *The Electrician*, May 15th, p. 34), but they have been somewhat modified by M. Picou. Each Gramme ring armature (2 metres in diameter) has an output of 1,000 amperes and 100 to 120 volts. The two armatures are coupled in series, the distribution taking place at 220 volts on the three-wire system. The machines run at 120 revolutions. The boilers, which are of the Belleville type, are situated in the basement, and the switchboard is on the first floor.

The Société Générale des Téléphones has thought it advisable to announce to the public that the malicious rumours which have been spread with regard to it are without foundation; the Société Générale has not raised the price of its instruments, and does not intend to do so, in spite of the recent decision in the law courts confirming the validity of its patents.

Electricity was well represented at the *fête* given at the Conservatoire des Arts-et-Métiers, on the 25th ult., to celebrate the centenary of the French patent system. The rooms were lighted for the first time from the mains of the Edison Company, and the Société du Théâtrophone had installed a post which was in telephonic communication with the principal theatres. The Société Générale des Téléphones exhibited samples of submarine cables manufactured by them, and amongst the apparatus of historic interest were the first Serrin lamp of 1853, a single-fluid sulphate of mercury cell, made many years ago by Antoine and Edmond Becquerel, and models of the original Planté accumulator and of the original Gaulard transformer.

As a result of considerable cross-questioning in the Chamber of Deputies, M. de Selves has practically disavowed the circular which you published on p. 94 of your last issue, and has now issued the following announcement: "In sending you the circular letter of April 21st, the Administration thought that you would be able to come to an understanding with the Société Générale des Téléphones with regard to the purchase of the telephonic apparatus installed at your house by that Société. Agreement not having proved possible, things will remain in their present state until the termination of the action now pending between the Administration and the Société. But I must ask you not to lose sight of the fact that there is need for you to put yourself in order, as your present position is not in accordance with the undertaking made by you when signing the subscription policy with the State, article 5 of which is as follows. . . . ."

* For descriptions of these meters see *The Electrician*, Vol. XXII., p. 393 (Aron); Vol. XXVI. p. 332 (Thomson-Houston); Vol. XXV., p. 254 (Frager); Vol. XXV., p. 619 (Marès).

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

"THE ELECTRICIAN"

ELECTRICAL TRADES' DIRECTORY & HANDBOOK for 1891.

The 1891 edition of our well-known Directory and Handbook is ready, price 5s., postage extra. The book consists of over 900 pages, and has entailed this year a heavy amount of work. The HANDBOOK DIVISION contains a mass of most useful information. The DIRECTORY DIVISION consists of 430 pages, and contains a very carefully compiled Alphabetical and Classified List of Firms and Persons engaged in the Electrical and Allied Trades in all parts of the world. This Division has been corrected up to date, and the book is thoroughly reliable, the very numerous changes which take place at the beginning of the year being incorporated. By the aidl of this Directory, makers of Electrical Machinery, Apparatus, Instruments, Fittings, Sundries, Novelties, and other goods, may safely communicate direct with probable customers without the annoyance and great expense consequent upon using books which are mere lists of Members of Scientific Societies repeated again and again. The Colonial and Foreign Division of this Directory will be found extensive and reliable. *Orders should be forwarded at once.*

In the course of a few days "The Electrician" Company will publish "THE ELECTRICIAN" PRIMERS in two volumes, price per volume 2s. paper covers, 2s. 6d. cloth.

PLANT FOR SALE.—Our advertisement columns contain particulars of some first-class electrical plant to be disposed of.

DISSOLUTION OF PARTNERSHIP.—The partnership between Mr. Carrington R. J. Smythe and Mr. Ernest Payne, carrying on business at 140, Bath-street, Glasgow, as electrical and mechanical engineers, has been dissolved.

TENDERS INVITED.—The Local Board for the District of Bishop's Stortford invite tenders for lighting the public streets at present lighted for one year from August 16th. Particulars may be obtained from the clerk, Mr. W. P. Slater, to whom tenders must be delivered not later than 10 a.m. on June 20th.

———. The Commissioners of H. M. Works, &c., invite tenders for the execution of pneumatic and electric bellhangers' work for public buildings, &c., in the London district, for three years from July 1st. Printed schedules and forms of tender may be obtained at H. M. Office of Works, 12, Whitehall-place, S.W., where tenders, addressed to Mr. H. W. Primrose, must be delivered by noon on June 15th.

———. The North-Eastern Railway Company request tenders for supplying telegraph stores for the six months ending December 31, 1891. Forms of tender may be obtained from Mr. Graves, Telegraph Department, York, to whom tenders must be delivered by noon on June 8th.

———. A notification will be found in our advertisement columns that all those interested in the electric lighting of Brussels may obtain a copy of the specifications on applying to the Bureau d'Electricité, 11, Rue de l'Etuve, Brussels.

INTERNATIONAL OKONITE COMPANY, LIMITED.—This Company announce that the extensive additions to their English factory at Newton Heath, Manchester, are now almost completed, and that they will shortly be in a position to offer for trial samples of okonite-covered wires and cables. The Company are manufacturers of every description of insulated wire, either vulcanised, india rubber, gutta percha, or compound, for electric light, power, telephone, or telegraph purposes, and notify in a circular issued to the trade that the okonite dielectric is merely another branch of their existing business. This circular continues:—"In addition, we have erected the most powerful and complete lead covering plant at present in use in Great Britain. We understand that a circular has been issued by a firm of electrical engineers which appears to some of our customers to convey the impression that we are intending to discontinue entirely the manufacture of ordinary high-class vulcanised wires in favour of okonite, and we particularly wish to inform you that this is not the case. On the contrary, we have more than trebled our plant for the production of vulcanised rubber covered wires. We have no special preferential agents, but propose to sell to the trade on as low terms as possible, making allowances for any special orders by way of extra discount. We state in our catalogue (now ready) the E.M.F. which each particular class of vulcanised wire is capable of sustaining, and we are prepared to guarantee this. Should any wire supplied not come up to the standard test we will at once replace it, as our main object is to keep up the highest reputation possible for quality and efficiency."

MESSRS. W. H. ALLEN AND CO.—This firm have secured the contract for the whole of the work in connection with the lighting of the Orient Steam Navigation Company's new twin-screw steamer, "Ophir," which is to be fitted out in a most complete manner. The installation will be a most extensive one, and Messrs. Allen and Co. will supply and install everything in connection with it. There will be four engines and dynamos of the "Allen" patent type. The engines are of the twin compound form constructed for high economy, the dynamos being of the Allen and Kapp improved construction, each capable of giving 300 amperes at 67 volts when running at 230 revolutions. There will be between 900 and 1,000 lights, as well as a projector for use when steaming through the Suez Canal, and mast head and side lights. The whole of the fittings in the saloon will be gold-plated and of an ornamental character, and the work throughout is to be of a most substantial description, similar to that for which Messrs. Allen and Co. have now established a well-earned reputation.

UNITED TELEPHONE COMPANY OF THE RIVER PLATE, LIMITED (IN VOLUNTARY LIQUIDATION).—A meeting will be held at 53, New Broad-street, E.C., on July 1st, at 12 noon, for an account of the winding up.

"ACADEMY ARCHITECTURE."—We have been favoured with a copy of this annual review, which is, no doubt, well known to many of our readers, and which consists of the most prominent architectural drawings hung at the Royal Academy Exhibition, and also contains a view of interesting architectural subjects carried out or designed during recent years in England and abroad. The issue for 1891 is larger than either of its two predecessors, and contains a very large number of handsome designs. The book will be found of use to many outside the architectural profession.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

May 11, 1891.

8,048. R. KENNEDY. Glasgow. Improvements in dynamo electric generators.

8,053. C. W. R. HAWKESWORTH. Horsforth, near Leeds. An electro-magnetic stop motion, applicable to machinery used in the spinning, twisting, or the doubling, winding of silk, cotton, wool, worsted, flax, jute, hemp, or other fibrous materials.

May 12, 1891.

8,102. J. A. F. ASPINALL and H. A. HOY. London. Improvements in arrangements by which a passing locomotive or train will cause a current of electricity to be transmitted for actuating signals and for other purposes.

8,126. G. J. PHILPOTT. Brighton. Improvements in compound dynamo-electric generators.

8,136. J. CHRISTIANSEN. London. Improvements in electric car motors.

8,141. W. P. THOMSON. Liverpool. Improvements in or relating to treating or manufacturing certain forms of insulated electric conductors (J. B. Williams, United States).

8,150. SIEMENS BROTHERS AND COMPANY (LIMITED). London. Improvements in rotary phase alternative current motors (Siemens and Halske, Germany).

8,151. SIEMENS BROTHERS AND COMPANY (LIMITED). London. Improved means for distributing rotary phase alternating currents to different current consuming apparatus (Siemens and Halske, Germany).

8,153. SIEMENS BROTHERS AND COMPANY (LIMITED). London. Improved means for carrying electro-motors on electrically propelled cars or vehicles (Siemens and Halske, Germany).

8,163. M. W. DEWEY. London. Improvements in electric railways.

May 13, 1891.

8,183. H. D. FITZPATRICK. Glasgow. An improved electric alarm and announcing clock for hotels and factories (S. Schubardt, Germany).

8,198. R. H. HOUSMAN, C. W. DIXON, and S. H. HOLDEN. Birmingham. An improved electricity meter.

8,215. E. J. HOUGHTON. Dulwich. Improvements in single needle speaking telegraph instruments.

8,218. A. R. SENNETT and F. W. CANNON. London. Improvements in dry batteries.

8,225. J. A. F. ASPINALL and H. A. HOY. London. Improvements in arrangements or apparatus for starting, working, and stopping or controlling signals by electricity, also applicable for other purposes.

8,227. W. P. THOMSON. Liverpool. Improvements in electrodes for electric accumulators (H. O. Tudor, Germany).

May 14, 1891.

8,256. P. L. RENOUF. Coventry. Improvements in brazing electrically, such improvements being particularly applicable to the frames of velocipedes.

8,258. H. C L. HOLDEN. Woolwich. Improvements in the construction of electrical vent sealing tubes for firing ordnance and for like purposes.

8,272. J. C. RICHARDSON. London. Electro-magnetic inductography and the electric transmission of light images or telephotography.

8,323. J. GOLDSMID. London. Improvements in thermo electric apparatus (V. Riatti, Italy).

May 15, 1891.

8,363. C. KAHN and W. DANGERFIELD, trading as The National Silex Optical Company. London. Testing sight for astigmatism by means of an electric worked card or disc.

8,378. H. SOUTH. London. Improvements in or relating to resistances for electric current circuits.

8,383. F. MÜLLER and W. GENEST. London. Apparatus for automatically actuating telephones on insertion of coin in payment for the use of same.

8,386. A. T. COLLIER. London. Improvements in microphonic or telephonic transmitters.

8,390. S. TAKASHIMA. London. Improved electrical apparatus for signalling the approach and departure of railway trains.

8,397. W. F. TAYLOR. Croydon. Improvements in methods of automatically regulating alternating current dynamo generators.

8,401. C. N. STANILAND and C. J. STANILAND. London. Improvements relating to electro-photography and to electro-photographic apparatus, applicable also to the preparation of printing surfaces.

8,405. W. W. HORN. London. An improved switch tongue adjuster (J. Mowder and J. S. Mowder, United States).

8,412. W. C. JOHNSON and S. E. PHILLIPS. London. Improvements in the armatures of dynamo-electric machines.

8,413. J. CLEGG. London. Improved means of regulating the preparation of illuminants for incandescent electric lamps.

Digitized by Google

May 16, 1891.

8,420. A. Hoster. London. Improvements in or relating to electric hair or skin brushes.

8,457. G. A. Spokes. Northampton. Improvements in electric arc lamps.

8,482. A. S. Bower. London. Improvements in and connected with moulds for casting, more especially intended for use in casting plates for secondary batteries.

May 19, 1891.

8,499. R. E. B. Crompton. London. Improvements in apparatus for controlling electric currents.

8,540. T. J. Moore and E. A. Warren. London. Improvements in conductors for electric railways.

8,555. W. P. Thomson. Liverpool. Improvements in insulated electric conductors (J. B. Williams, United States).

8,573. J. Y. Johnson. London. The manufacture and production of hydrocarbon products or compositions for use for insulating or other purposes (J. Weir, United States).

8,579. C. B. Harness. London. An improvement relating to electrical belts, chiefly designed for medical purposes.

May 20, 1891.

8,609. T. Smith. London. Improved pipes or leads for electric conductors.

8,648. E. Bazin. London. Improvements connected with the use of compressed air for producing electric light and cold.

May 21, 1891.

8,659. A. H. Rowan. London. Improvements in electric tramroads.

8,664. C. Sigmund, Knight of Ilanor. London. An improved storage cable.

8,680. C. W. Cox, W. Robinson, and W. H. Gritton. Liverpool. Improvements in or appertaining to the lighting of ships' signal lamps by electric light.

May 22, 1891.

8,722. J. G. S. Cunnington. London. An improved form of carrier for shades and globes for gas and electric light.

8,735. E. W. Berdoe and G. M. Shum. London. Improvements in electrical storage batteries or accumulators.

8,742. R. Hope-Jones. Liverpool. Improvements in electrical organs or similar instruments.

May 23, 1891.

8,784. S. Evershed and A. E. G. Richards. London. Improved means of, and apparatus for, the transmission of telegraphic signals.

8,798. F. Hanusse and G. Borrel. London. Improvements in electrical signalling apparatus.

8,806. A. I. Gravier. London. Improvements in dynamo-electric and electro-dynamic machines.

8,808. W. J. Green. London. Improvements in and relating to electrical batteries.

8,811. G. Mengarini. London. Improvements in and relating to electric meters.

8,812. A. Hoster. London. Improvements in or relating to casing and covers for electric wires.

COMPANIES' MEETINGS & REPORTS.

The Notting Hill Electric Lighting Company (Limited).

The annual general meeting of the shareholders of this Company was held on Saturday, 30th May, at Bulmer-place, High-street, Notting Hill, under the presidency of Prof. Wm Crookes, F.R.S.

The SECRETARY read the notice convening the meeting. The minutes of the previous meeting, and the Directors' report and statement of accounts, were taken as read.

The CHAIRMAN: Gentlemen, this is an important meeting in our history, for we to-day inaugurate a system of lighting which I trust will go on continuously night and day for the parliamentary term of 42 years. In formally moving the adoption of the report and accounts, I may mention that the accounts are in the form prescribed by the Board of Trade. From the heading of Form 3, as explained in the Directors' report, it will be seen that the expenditure covers a period of nearly three years, dating from the incorporation of the Company in February, 1888, but the greater part of the expenditure has been incurred during the past 12 months, in erecting the works and machinery and laying the mains. The items in this account speak for themselves, but I may make a few remarks as to the purchase of the Victoria gardens and Bulmer-place properties. Having the opportunity of purchasing the freehold of the Victoria-gardens site, the Directors considered it would be to the interests of the Company to do so, and they therefore effected the purchase as cheaply as possible. A portion of this property is let to Messrs. Sanders, who were interested in the sale. It will also be noticed by the report that it was found desirable to purchase the lease of seven small houses in Bulmer-place, adjoining the works. This was done to avoid waste of time in the erection of the works, as considerable delay was occurring in consequence of injunctions obtained by the owners of the Bulmer-place property against the Company proceeding with the works. I may mention that all the houses are occupied, chiefly by men employed at the Company's central station. In the erection of the central station, 10,000 loads of earth have been removed, and there have been used 1,450 cubic yards of concrete, 700,000 bricks, and 115 tons of ironwork. At present, two boilers 350 H.P. each, two boilers 70 H.P. each, three engines and dynamos, together can supply houses containing 12,000 lamps. The battery station at Phillimore-mews will raise the capacity to 18,000 lamps. Three more boilers and dynamos (costing £6,500) will raise capacity to 50,000 lamps. The Directors very much regret the delay in completing the works, and have done their utmost to overcome the difficulties causing the delay. But as soon as the injunctions were disposed of the exceptionally severe weather of last winter was upon us, making it impossible for the contractors to proceed with the work. The mains have been laid in the principal part of the compulsory area, and comprise about three miles of culverts and five miles of cable. Working, as we do, on the three-wire system, we have thus laid about nine miles of copper strip, or a total of 14 miles of conductor, containing, altogether, 67 tons of copper. The estimated cost of laying the mains has been somewhat exceeded, owing to it having been found absolutely necessary to put down cable instead of strip in many of the streets and roads. I may say that the number of houses wired for lamps is 70; number of houses wired, by which our mains pass, 60; number of lamps, reduced to 8 candles, in houses already wired, about 5,000; number of lamps, reduced to 8 candles, in wired houses, by which our mains now pass, 3,500; estimated number of lamps on our mains by the end of the year, 7,500; estimated revenue per 8-candle lamp per annum, 10s.; estimated income from 7,500 lamps, £3,750. It is proposed to extend at once to Westbourne-grove. This will bring in a further revenue of about £300 a year. An accumulator station is being arranged for in Phillimore-mews. This will give us greater facilities for supplying houses in our southern district. A new site for the second central station is in treaty for near Addison-road. This will give us command over the rich district of Addison-road, Addison-gardens, Melbury-road, and the two acres of good houses which are to be erected in Holland Park. The Directors have every reason to hope that this second station will be self supporting from almost its commencement. The Directors have made an application to the Committee of the Stock Exchange for a quotation of the Company's shares on the official list, and we have every reason to believe this will soon be granted. The delay has arisen owing to the necessity of being able to say that the works were actually open and supplying current. Not a single fault or leakage has been found in our system of mains. This speaks well for the excellence of the mains and cable, and the skill and care of the engineering staff. The light has been supplied to a few houses, experimentally, for some weeks, during which time it has been subjected to careful tests as to steadiness and uniformity. No fault has been detected. For the present we expect to run entirely from batteries, which will be charged a few hours a day, increasing as the load increases. At present we charge the batteries for two hours a day. I move:—

"*That the report of the Directors, and the accounts for the period commencing February 21, 1888, and ending December 31, 1890, submitted to this meeting, be, and the same are hereby, approved and adopted.*"

Mr. SIDNEY WATERS seconded the motion.

Mr. GAMBLE thought that £4,000 was a very large sum to pay for the license, provisional order, and preliminary expenses. With regard to the general balance-sheet, he found that, after spending apparently all the money that had been raised, they had still a deposit at the bank of £6,000. How was that to be explained?

The CHAIRMAN: In reply to the first question, I may say that the item includes the whole of the preliminary expenses. These extended over

Digitized by Google

two years, and in addition to the usual charges connected with registration, advertising, and brokers' fees, include heavy law costs, counsels' fees, and Parliamentary agent's expenses incurred during the long fight before the Board of Trade and both Houses of Parliament.. This item appeared in the original prospectus issued to the public in January, 1890. At the 31st December, 1890, we had spent £43,126, and we had £6,666 cash in hand, and there was uncalled capital as well to the amount of about £27,444.

Mr. GAMBLE: Share capital?

The CHAIRMAN: Yes, ready to call.

Mr. GAMBLE: But still I cannot see how that amount of cash can be at the bankers.

The CHAIRMAN: It was there in cash on December 31st.

The SECRETARY said that as against the cash in hand they had certain liabilities which had to be met out of it. It was a mere question of book-keeping.

Mr. FRANKLIN explained that the Board of Trade compelled them to close their books on December 31st, at which date there were some people to whom they owed certain bills, and the money was merely lying at the bank ready to be drawn.

Mr. REEVES asked whether it was possible for the Chairman to say when the Company would be able to supply current to the Phillimore estate.

The CHAIRMAN: The engineer will probably answer that.

Mr. REEVES: Probably you will do so in the course of next winter.

The CHAIRMAN: I scarcely think it will be so long as that.

The ENGINEER (Mr. J. Crookes): It will take about eight months to do so.

The resolution was then formally put to the meeting, and carried unanimously.

The CHAIRMAN: According to our Articles of Association two of the Directors retire by rotation, and, being qualified, they offer themselves for re-election. I therefore move—

"*That the retiring Directors, Messrs. Alexander Howden and James Thomas Jarvis, be re-elected.*"

Mr. ROMER seconded the motion, which was agreed to *nem. con.*

Mr. HOWDEN, in acknowledging the re-election of himself and colleague, assured the meeting that nothing would be wanting on their part to merit the renewed mark of confidence of the shareholders.

On the motion of Mr. BENSON, seconded by Mr. REEVES, the auditors, Messrs. Deloitte, Dever, Griffiths and Co., were unanimously reappointed.

Mr. GAMBLE proposed, and Mr. ROMER seconded, a vote of thanks to the Chairman, which was cordially passed.

The CHAIRMAN briefly acknowledged the compliment, and the business of the shareholders' meeting ended.

A meeting of the general public of the district to be supplied by the Company was held afterwards in the main building of the works, to hear a statement from Prof. Crookes, explanatory of the Company's operations, and the principle on which the electric light is to be supplied, and to formally turn on the electric current. There was a large attendance of both ladies and gentlemen, and

Prof. CROOKES, who received a cordial reception, spoke very hopefully of the prospects of electric lighting generally, and in reference to the prospects of the Notting Hill Company in particular. He related how, about 10 years ago, he inaugurated probably the first installation of the electric light in a private dwelling. He remembered, when the excavations were being made for the dynamo and engine, that there was very great curiosity in the neighbourhood as to what he was doing, and the very workmen who were doing the work got rather confused between dynamo and dynamite; in fact, there was a report in the district that he was making a dynamite factory, and the consequence was that his immediate neighbours began to get rather anxious. But that time had now passed away. Prof. Crookes then gave the meeting a general idea of the plant necessary for lighting a large district, and showed how fully the Notting Hill Company had provided for eventualities, claiming for his Company all the advantages of the low-tension system. If you took it light for light, the electric light was not as cheap as gas, any more than wax candles were. But it was really much cheaper than gas if incidental savings were taken into consideration. Thus, with electricity the ceilings do not get blackened, the wall papers do not become soiled, the curtains and drapery do not get dirtied by smoke, decorative paintwork is not deteriorated, gilding remains as fresh as when first applied, bindings of books are not rotted, and oil and water colour paintings are not injured by the sulphur of gas; the air we breathe in the room is always sweet and fresh and is not loaded with hot products of combustion, while fire risk is almost annihilated, as no matches are required. If anyone present would reckon up what he pays every year under the above headings, and add the amount to his average gas bills, he would find that the expense of electric lighting was far below that of gas. Another saving was effected owing to the electric light being so easily turned off and on. With the switches near the door, as they ought to be, one soon gets in the habit of turning the lights off when leaving a room, and only turning them on on entering. No matches being required, this involved no trouble.

Prof. Crookes concluded his interesting discourse amid the hearty plaudits of the assembly, and a cordial vote of thanks was passed to Prof. and Mrs. Crookes and the other Directors of the Company, for having so successfully carried out and launched their undertaking; and, in reply, Prof. Crookes asked that full credit should be given to his co-directors, who had worked very hard to bring about the success which he had been able to chronicle. Their thanks were also especially due to their engineers, Messrs. Crompton, and to Mr. J. E. Spagnoletti and to their secretary, Mr. Fox. Mr. Schultz was the resident engineer, and they could see the kind of work he had done. Mr. Slater, the architect, had done wonders, too, in getting an immense mass of machinery, batteries and appliances of all kinds, into rather limited space. To all these gentlemen their thanks were due. The audience, having inspected the works and plant, then dispersed.

Anglo-Portuguese Telephone Company (Limited).

The following is the report of the Directors, to be presented at the adjourned fourth ordinary general meeting of the Company, to be held at the offices of the Company, 53, New Broad-street, E.C., on Thursday, the 11th June, 1891, at 3 o'clock p.m.:—

The Directors beg to submit to the shareholders their report and accounts of the Company for the year ending December 31, 1890. The amount to the credit of profit and loss account, after making all deductions, and including the balance brought from last year, is £6,193. 15s. 6d. Out of this an interim dividend of 5 per cent. has since been paid, absorbing £2,500, and of the balance it is now proposed to place £2,500 to reserve, and to carry forward £1,193. 15s. 6d. to the current year's accounts. The expenditnre on capital account for the year amounted to £6,589. 4s. 9d.

The number of paying subscribers at December 31st last was—in Lisbon, 1,024, of a gross annual value of £7,530; in Oporto, 983, of a gross annual value of £5,391, £12,921, showing a total increase in subscribers of 152, and in value of £1,033, over the preceding year.

The Directors are pleased to announce that the Conde De Gouveia and Mr. Pinto-Basto have rejoined the Lisbon Board, and that Dr. Marcal Pacheco has been re appointed the Company's legal adviser in Portugal. Mr. C. L. W. Fitzgerald, of the London Board, and the Conde De Gouveia, of the Lisbon Board, are the retiring Directors at the forthcoming general meeting, and, being eligible, offer themselves for re-election. The auditors, Messrs. Deloitte, Dever, Griffiths and Company, being eligible, offer themselves for re-election.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The Directors of this Company have declared an interim dividend of 5s. per share, free of income-tax, for the quarter ended March 31st last, and payable on the 24th inst. The transfer books will be closed from the 17th to the 23rd inst., both days inclusive. The traffic receipts of this Company for the past week amounted to £4,794.

CITY AND SOUTH LONDON RAILWAY COMPANY.—The traffic receipts of this Company for the past week amounted to £768. The aggregate receipts for the half-year to date are £16,143.

CUBA SUBMARINE TELEGRAPH COMPANY.—The estimated traffic receipts of this Company for the month of May were £3,600, as compared with £3,409 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY.—The traffic receipts of this Company for the month of May, 1891, amounted to £2,163, as against £2,244 in the corresponding period of last year, or a decrease of £81.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this Company for May were £53,829, as against £53,373 for the same period of 1890, an increase of £456.

EASTERN EXTENSION TELEGRAPH COMPANY.—The receipts of this Company for May amounted to £37,064, as against £41,230 in the corresponding period of last year, showing a decrease of £4,166.

ELECTRIC AND GENERAL INVESTMENT COMPANY (LIMITED).—A notice appears in our advertisement columns that the share transfer books and register of members of this Company will be closed from June 3rd to June 17th, both days inclusive, for the purpose of preparing the dividend cheques.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this Company are as follows:—Receipts in May, 1891, £26,000; 1st January to 31st May, 1891, £114,000; corresponding months, 18.0, £105,800; corresponding months, 1889, £106,800.

NEW COMPANIES REGISTERED IN MAY.—Out of a total capital of £9,867,618 in new companies registered during May, electrical undertakings are, says the *Financial Times*, reponsible for £311,000.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended May 29, 1891, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,879.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this Company for the two weeks ended May 31st amounted to £2,779, as compared with £3,256 for the corresponding period last year, showing a decrease of £477.

CRICKET.—Woodhouse and Rawson United (Limited) v. The Electric Construction Corporation (Limited).—A match between these elevens was played on Saturday last, at Walthamstow, and ended in a victory for the former. Scores:—

ELECTRIC CONSTRUCTION CORPORATION (LIMITED).—Shaw (leg b w, b Tasker) 27, Fraser (run out) 13, Spears (b Sellick) 0, Sage (b Foley) 13, Clark (c Moore, b Howell) 14, Davidson (b Long) 5, Oxley (c and b Long) 1, Collins (b Long) 1, Frower (not out) 0; extras, 9—total 83. (E. C. C. batted two short).

WOODHOUSE AND RAWSON UNITED (LIMITED).—A. L. Foley (b Sage) 22, H. C. Foy (b Sage) 4, W. R. Long (not out) 40, R. D. Holtz (b Sage) 9, Tasker (not out) 1; extras, 10—total 86. Stutchbury, Taylor, Sellick, Moore, Jones, and Howell did not bat.

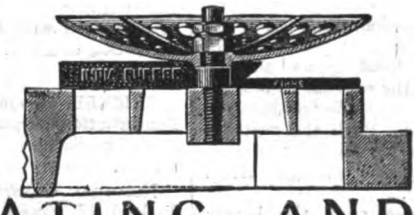
NEW VALVE



No Rubber, Percha, or Leather.

One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept. 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to MOSSES & MITCHELL, 68-71, Chiswell Street, London.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 682.—Vol. XXVII. FRIDAY, JUNE 12, 1891. Price Fourpence.

NOTES.

On Tuesday last the unusual process of reviving a patent by a special Act of Parliament was exemplified by the third reading and passing of the Worms and Balé Patent Bill in the House of Lords. It will be remembered that the British Tanning Company, who are the owners of this patent, and who have been engaged in the tanning of leather on a considerable scale with the assistance of electricity, brought an action against Mr. Groth for infringing their patent, which practically consists in the use of a rotating drum containing the hides and liquor. But while they failed to show an infringement, their patent was invalidated by prior publication, through an American patent abridgement. The patentees had omitted to avail themselves of the then newly-constituted International Convention, and thus lost their patent. Had the action of the British Tanning Company *v.* Groth (which was fully reported in *The Electrician*, p. 341 and p. 369, Vol. XXVI.) shown that the invention of Worms and Balé consisted in the wider idea of the combination of electricity and motion, the revival of their patent would be a matter of very considerable importance, for the effect of an electric current in hastening the process of tanning is well established, and it might have been held that such a combination was actually a "method," and not a principle; but no such broad claim was made, and the revived patent must be restricted to the use of the revolving drum.

The researches of Dr. Lodge in connection with the subject of lightning discharge have been very fully treated in *The Electrician*, but it seems that the experiments have been even more numerous than those hitherto published. In a lengthy Paper, read at the last meeting of the Royal Society, the learned Professor gave a detailed account of a number of his earlier experiments. Many of these, it is true, have been previously described, but the actual measurements made, and the practical details of the apparatus, have not been published before. These early experiments are of special interest, as they deal with the subject of electro-magnetic waves, and clearly show how very near Dr. Lodge was to foreatall Prof. Hertz in his important work. Indeed, if it had not been for the fact that the mind of the English investigator happened to be bent on the study of lightning conductors, the probabilities are that most of the discoveries of Hertz would have been arrived at simultaneously and independently by the two physicists. Even as it is, the work of Dr. Lodge is so similar to that of Prof. Hertz that the names of the two investigators will always be linked together in describing the epoch in electrical science brought about by their efforts. We may call attention to the fact that Prof. Lodge will show "some experiments with Leyden jars" at to-day's meeting of the Physical Society, and those of our readers who are able to attend will have the opportunity of seeing some interesting experiments.

At the same meeting of the Royal Society a Paper on "Quadrant Electrometers," by Profs. Ayrton and Perry, and Dr. Sumpner, was read and discussed. It describes an investigation which has taken a long time to complete, and contains a considerable amount of much-needed information with reference to the behaviour of electrometers when the potential of the needle is varied. It has been known for some time that the ordinary law, given in mathematical text books, connecting the deflection of the instrument with the potential of the needle, and the voltage between the quadrants, is not fulfilled, and that, in consequence, the instrument cannot be used for the measurement of power supplied by alternate currents. The extent to which the law is inaccurate, and the circumstances which influence the error, have, however, not been at all well understood, and few experiments have been made on the subject, as they are difficult to carry out. These matters have been thoroughly investigated, and we shall refer to them at greater length when the complete Paper appears in print. In the meanwhile, the chief results of the work may be very briefly summarised. According to the authors of the Paper, the chief cause of the peculiar behaviour of the White electrometer is the electrical action between the guard tube and the needle, and also the slight tilting of the needle which occurs at high potentials. The writers also make the important observation that, according to the adjustments of the quadrants, the deflection, for a given difference of potential on the quadrants, may be made either nearly independent of the potential of the needle or directly proportional to it, or to increase more rapidly than the potential of the needle. In one case the adjustment of the quadrants was such that the deflection did not alter appreciably, while the potential of the needle was raised from 2,000 to 3,000 volts.

A description is given of an improved form of instrument, in which the errors due to the presence of the guard tube are eliminated, so that the ordinary law is fulfilled. In this instrument the control is magnetic, as in the original specimens of the quadrant electrometer. The bifilar arrangement, afterwards adopted by Sir William Thomson, has been abandoned, because

Digitized by Google

the authors find that greater sensibility can be obtained with a unifilar control, while external magnetic disturbances can be sufficiently reduced by using an astatic combination of magnets on the moving parts of the instrument.

MR. MERRITT'S note, which we publish in this issue, relates to the behaviour of galvanometers while the needle is actually in motion. Neither the phenomena described, nor the explanation given of them, present any striking points of novelty. When a current is suddenly passed through the coils of a galvanometer the needle swings about its new position of equilibrium for some time; and if, while this action is going on, the current itself varies, the motion of the needle is compounded of the motion corresponding with the change of current strength, and that corresponding with the natural oscillations of the needle. Moreover, if the variation of the current takes place according to any fixed law, the magnitude of the first swing must always be proportional to the final deflection of the needle. The experimental proof of these statements is, however, a matter of some interest, and Mr. MERRITT has done well to call attention to the considerable saving in time and gain in accuracy which can often be obtained by making use of the first swing, instead of the final deflection, for purposes of measurement. In Mr. MERRITT'S valuable investigation on the energy of the light given out by glow lamps, the method was used chiefly on account of its rapidity, as many sources of error were thereby eliminated. The swing method in these experiments was less sensitive, because of the final deflection being greater than the initial impulse of the needle. Sometimes, however, the reverse holds good, as, for instance, when the value of a steady current is estimated from the swing produced by suddenly passing it through the coils of a galvanometer. Here not only is the time necessary for an observation much less, but the actual deflection is generally twice as large.

Royal Meteorological Society.—Notice of Removal.—On May 20th, the offices and library of this Society were removed from 30, Great George-street, to more commodious rooms at 22, Great George-street.

Electric Traction in Spandau.—A 50 years' concession for working electric railways in Spandau has just been granted to the International Electric Company of Boston. Work has to be commenced within three months.

Electrical Bills in Parliament.—The following Bills were read a third time in the House of Lords during the week and passed:—London Overhead Wires Bill; Electric Lighting Bills Nos. 1, 2, 3, and 4; Worms and Balé Patent Bill.

Lightning.—A company of soldiers at drill, near Berlin, were struck by lightning on Tuesday morning. A great number of soldiers were rendered insensible, the captain's horse was killed, and a soldier who was holding the bridle was dangerously wounded.

Larne.—At a special meeting of the Town Commissioners, last week, the tender of Messrs. Gordon and Co. to light the town with 10 arc lamps of 1,200 c.p. each, and 49 incandescent lamps of 16 c.p. each, for the sum of £200 per annum, from 1st August to 30th April, was accepted.

Compagnie Francaise des Telegraphes Sous-Marins.—The "Westmeath" has laid the Puerto-Plata-Martinique section of this Company's cable system, and the "Ludaate" has just sailed for the West Indies with the section connecting Guiana with Brazil.

Small Electric Motors.—The *Elektrotechnischer Anzeiger* states that the Berliner Elektricitätswerke is about to reduce its charges for motive power, so that small electric motors will be able to be run at a lower cost than those using any other form of energy.

Liverpool.—At the last monthly meeting of the City Council the Watch Committee brought forward a scale of charges for testing lines and mains, recommended by them to be made under the Liverpool Electric Lighting Order, 1889, and this schedule was passed without discussion.

The Paris Telephone Exchange.—The building of the Paris Central Telephone Exchange, says our Paris correspondent, is proceeding with great rapidity, and the shell will be completed by the autumn, and the exchange come into operation by the beginning of 1892.

Overhead Electric Traction Wires and the Telephone.—The German postal authorities are about to institute proceedings against the Allgemeine Elektricitäts Gesellschaft, owing to the disturbances caused in telephonic circuits by the Company's electric tramway at Halle, on which the Sprague system is used.

Newcastle.—At a meeting of the Town Council, last week, the Town Clerk reported that the petition against the Newcastle Electric Lighting Bill had been sent to the Board of Trade, and they had received a letter from the Board of Trade to the effect that they had conceded all the points in the petition

Copper.—The price of fine bars, which was £51. 12s. 6d. at the end of April, had advanced to £55. 5s. by the end of last month. The supplies during May amounted to 9,672 and the deliveries to 11,180 tons. The stocks in hand are now 57,808 tons, as against 59,316 tons at the end of April and 82,041 tons this time last year.

The Austrian Society of Electricians.—At the end of 1890 this Society consisted of 569 members, of which 255 inhabit Vienna, and 207 inhabit the provinces, 107 being foreign members. The annual revenue of the Society is £640, of which £420 comes from subscriptions and £110 from the sale of the journal, the cost of the bringing out of which amounts to £360.

The Faraday Centenary.—The Prince of Wales has fixed 4 o'clock on Wednesday, June 17th, for the delivery by Lord Rayleigh of the first of the two lectures at the Royal Institution in connection with the centenary of the birth of Michael Faraday, and Friday evening, June 26th, at 9 o'clock, has been appointed for the second of these lectures, which will be given by Prof. Dewar.

The Telegraph Battalion of the Royal Engineers.—The 1st Division of this Battalion is engaged, as a summer exercise, in running a field telegraph line from Aldershot to Chatham. From Aldershot to Chevening, near Sevenoaks, a distance of 50 miles, the line was erected in less than 30 hours, which is said to be the smartest feat of the kind on record. Light bamboo poles are used as supports.

Obituary.—The death is announced of Dr. W. E. Steavenson, from influenza and bronchitis, on June 1st, at the age of 41. In 1883 he took office at St. Bartholomew's as casualty physician, and during this period was appointed physician to the newly-created electrical department at that institution, a post which he continued to fill to the day of his death. Dr. Steavenson wrote several Papers on subjects connected with the electrical treatment of disease, and last year he published his book on "Electrolysis in Surgery."

The North London Steam Trams.—These cars will shortly cease running in consequence of an agitation set on foot some months ago by the residents at Finsbury Park and neighbourhood. The Board of Trade has now refused to grant a renewal of the running powers of the North London Steam Tramways Company between Finsbury Park, Wood Green, and Edmonton. The steam cars were not running in accordance with Board of Trade requirements, and the engines were not kept in good order. They will cease to run on and after June 15th.

Royal Society.—The following Papers were down for reading before the Royal Society yesterday:—Sir William Thomson,

Digitized by Google

Pres. R.S., "On a Test Case of the Boltzmann-Maxwell Doctrine regarding Distribution of Energy." W. Crookes, F.R.S., "On Electrical Evaporation." G. H. Robertson, "A Study of the Planté Lead-Sulphuric Acid-Lead Peroxide Cell, from a Chemical Standpoint. Part I." Prof. Armstrong, F.R.S., and G. H. Robertson. "Part II.—A Discussion of the Chemical Changes occurring in the Cell." H. Wilde, F.R.S., "On the Influence of Temperature upon the Magnetisation of Iron and other Magnetic Substances."

York.—The members of the electric lighting committee and the streets and buildings committee of the York Corporation held a joint meeting last week, to consult with Mr. R. E. Crompton—who some time ago was appointed the consulting electrical engineer of York—on the proposed scheme for the introduction of the electric light into the city. Mr. Crompton was in favour of the low-pressure system. After considerable deliberation on the matter, Mr. Crompton was requested to furnish a report on the subject, with special reference to the cost of laying down the necessary plant, the cost of maintenance, &c.

Societe Generale des Telephones.—At the meeting of the shareholders of this Company, on the 3rd inst., a dividend of 18fr. per share was declared and 79,625fr. were carried to the reserve fund. MM. Lair and Viguier were re-elected Directors, and M. Lazare Weiler was authorised to remain a Director, while retaining his post of Managing Director of the Société des Usines d'Angouleme, which supplies a large amount of material to the Société des Téléphones. MM. Lair, May, Wallerstein, and Viguier, were similarly authorised, they being also Directors of the Compagnie des Télégraphes Sous-Marins. MM. Kulp, de Sainte-Marie, and Petit were re-appointed managers.

Electric Wires in Glasgow.—A very serious fire broke out, early on Monday forenoon, in Miller-street, Glasgow, which played sad havoc among telephone and telegraph wires. No less than twenty telephone lines were interrupted. Eleven of the wires were in connection with the National Telephone Company's local exchange, and the rest were private lines. Three fire-alarm wires were also destroyed, and Messrs. Muir, Mavor, and Coulson had to clear away one of the branch mains for supplying their customers with electric current. Although the main was in such close proximity to the fire only one customer was temporarily cut off.

Asbestos in New South Wales.—The Government Geologist of New South Wales, according to the *Sydney Morning Herald*, has received several samples of asbestos, which were discovered at Red Hill, near Broken Hill. The asbestos was obtained in a vein measuring from 2½ft. to 3ft. in width, at a depth of 10ft. from the surface. Some of it contains fibre 13in. long, the texture being silky and flexible. The Broken Hill material is not, however, as strong or tough as the Italian asbestos. The colour too, is different, as the Broken Hill asbestos is reddish in hue, owing to the presence of iron oxide. It is expected that a whiter mineral will be found at a greater depth. Several tons of asbestos have been brought to surface.

Cataphoric Medication.—It was César Antoine Becquerel says *L'Electricité*, who discovered the phenomenon of transportation by the electric current, and who utilised it before 1830 in the artificial formation of crystals. A few years later he applied his discovery to the study of vegetable physiology, and investigated in a thorough manner the modifications produced by the electric current in the endosmose and exosmose of vegetable substances, and of membranes of animal origin. The scientific theory of the introduction of medicaments into the human body was in this way founded. The first direct application to medicine was made by Dr. Fabri-Pelleport, who died in 1838. Renewed attempts were made in London, in 1859, by Dr. Richardson, who extended his researches to aconite, morphine, and chloroform.

The Cultivation of India-rubber and Gutta-percha.—Something like 1½ tons of india-rubber were recently sold in Amsterdam, the product of trees planted about 10 years ago in Java. The prices obtained were said to be excellent. The care needed to cultivate rubber begets the same quality in gathering, remarks the *India Rubber World* of New York, and it is well known to manufacturers that many an inferior rubber would come into favour if it were not so full of rubbish, which requires expensive labour to eliminate. In Algeria the cultivation of the gutta-percha tree is to be begun by extensive planting of trees under the superintendence of French Government officials. As it takes a tree 25 years or more to reach maturity, the plantation of gutta-percha trees is not very likely to attract private enterprise.

The Fothergill Prize.—Under the will of Dr. Fothergill (1821), funds were bequeathed to the Society of Arts for the offer of medals for subjects, in the first instance, relating to the prevention of fire. A Society's gold medal, or £20, is now offered for the best invention having for its object the prevention or extinction of fires in theatres or other places of public amusement. In cases where the invention is in actual use, reference should be made to places where it could be inspected. A full description of the invention, accompanied by such drawings or models as are necessary for its elucidation, must be sent in on or before December 31, 1891, to the Secretary of the Society of Arts, John-street, Adelphi, London. The Council reserve the right of withholding the prize in case there is nothing in their opinion deserving the award, or sufficiently complying with the conditions, sent in for competition.

Electric Launches on the Thames.—On Monday afternoon last two additions were made to the Thames electric launch fleet by the floating, from the Strand Electric Launch Works, at Chiswick, of the "Glowworm" and the "Myiomi." These boats have been designed by Mr. W. S. Sargeant, branch manager to Woodhouse and Rawson United. The "Glowworm" is 53ft. long, with 7ft. 2in. beam, has a draught of 2ft. 6in., and displacement of 5¾ tons. She is built of bright mahogany with teak fittings. She will carry 40 passengers, make about nine miles an hour, is lighted as well as propelled by electricity, and carries a search light. The "Myiomi" is 35ft. long, with 5ft. 6in. beam, and 18in. draught, and a displacement of 3¼ tons. She is constructed of mild steel, with teak fittings; her electric arrangements are similar to those of the "Glowworm," but there is no search light. Her speed will also be about nine miles an hour.

The Electrolysis of Animal Tissues.—In a recent Paper on this subject, entitled "Studies from a Physiological Laboratory," Mr. G. N. Stewart says that it seems that practically the whole of the conduction in animal tissues is electrolytic, and the electrolytes are principally the mineral salts, changes in the proteids being produced by secondary electrolytic actions. In simple proteid solutions, conduction occurs with great difficulty if mineral salts are absent, or if they are present only in small proportions. The effects on the proteids themselves in saline solutions vary somewhat with the current density. The effects of electrolysis on the salts of the muscle were studied by estimating the ash. Striking changes were found to occur which, if produced within the living body, would profoundly modify nutrition. The antiseptic action of the current was studied in the case of micro-organisms, and it was found to occur chiefly, if not entirely, around the anode.

The Use of Incandescent Lamps in Connection with the Magnetograph.—In a recent number of *La Lumière Electrique* a description is given of the manner in which some small incandescent lamps, made by M. Trouvé, are used to replace the gas and petroleum lamps previously employed in the St. Petersburg Observatory as a source of light in connection with the Adie magnetograph. The necessary current is obtained from Jablochkoff accumulators, and special care has been taken to prevent the magnetic effect of the current disturbing the magnetometers. The advantages of employing incandescent lamps in this connection are briefly as follows:—The curves on the photographic paper are clearer, more uniform, and more sharply defined, consequently they permit of more precision. The substitution of electricity for gas or petroleum causes the troubles due to rise of temperature of the room to disappear. The arrangement is also more economical, and less troublesome to keep in order.

The Royal Alfred Aged Merchant Seamen's Institution.—Telegraphy was well represented at the festival dinner of this

Digitized by Google

Institution, which took place at the Hotel Metropole, on Wednesday evening last. Sir James Anderson occupied the chair, and, in the course of his remarks, made reference to his old association with the Cunard line, and was loudly cheered when describing his work on the "Great Eastern," while laying the Atlantic cables. He spoke very feelingly of the hard lot of the sailor, and appealed to his hearers to assist the Institution by providing it with the means of helping the seaman in his old age. The secretary (Mr. W. E. Denny) was able to announce that no less a sum than £4,107. 16s. had been collected, including a subscription of £500 from the chairman. This is a much larger sum than has ever before been announced at the Institution's Festival. Captain Halpin, on behalf of the Committee of the Institution, in thanking Sir James for presiding and for his handsome donation, gave some interesting details of his connection with the cable-laying expeditions referred to. Between 200 and 300 ladies and gentlemen were present, including captains of the cable ships at present at home.

Growth of Electric Lighting in Pittsburgh.—The following table shows the growth of the business of a Westinghouse station owned by the East End Electric Light Company, of Pittsburgh, The business of this Company is largely that of residence lighting, at least 75 per cent. of its lights being of this character :—

——	1886.	1887.	1888.	1889.	1890.
January	82	824	1,725	4,197	11,855
February	170	899	1,735	4,625	12,261
March	225	930	1,753	5,035	13,001

December	662	1,703	3,996	11,508	20,134

The Determination of Specific Heats by the Electric Current.—A method of determining specific heats by the electric current was published by Prof. J. Pfaundler in 1869. It depended on Joule's law, and was one in which the same current develops quantities of heat, in coils of wire arranged in series. This method has hitherto found but few applications from the circumstance that it only applies to non-conducting liquids. According to an article in the *Wiener Berichte*, Prof. Pfaundler has got rid of this drawback by substituting for the coils of wire spiral glass tubes filled with mercury. He has also given the method far greater accuracy and certainty by inserting three mercury resistances in the branches of a Wheatstone bridge, by which it is possible to control and keep constant the ratio of the resistances during the passage of the heating-current. Small variations in resistance are compensated by introducing glass threads in the straight ends of the tubes which contained the mercury. In other cases these changes are measured by displacing the contact-key, and in this way the result is corrected. The comparative measurement of the rise of temperature is made more delicate by means of a thermopile.

Hull.—A meeting of the Electric Lighting Committee of the Hull Corporation was held last week. The minutes of the sub-committee appointed to obtain information with regard to the best system of electric lighting recommended that an installation should be laid down by the Corporation on the low-tension three-wire system, and that the mains be laid in culverts, uninsulated. The minutes were discussed at considerable length, and on the motion of the Chairman it was resolved by a large majority to recommend the Council to empower the committee to at once take the necessary steps for laying down such an installation as might be desirable, on the lines of the sub-committee's report, at a cost not exceeding £22,000. Mr. R. E. Crompton, electrical adviser to the Corporation, was in attendance. In his report, he stated that he agreed with the committee that for the town of Hull the low-pressure system was the best one to adopt. In fact, he had seldom seen a town in which it could be carried out so easily and with such great advantage as in Hull. The position proposed for the central station was so well chosen that there was no inducement whatever to adopt the high pressure system with its many dangers and other disadvantages. It is proposed to employ Willans engines and Siemens dynamos.

Postal Telegraph Clerks' Association.—On Saturday last, the tenth annual conference of this Association was held in Edinburgh. There were present 55 delegates. Mr. Thomas Warder (Edinburgh) presided, and said that since the conference was held last year at Leicester several important concessions had been granted by the Postmaster-General, and for these they were grateful, especially for the payment for Sunday duty. Mr. T. D. Venables (Liverpool), secretary, read the annual report, which stated that the progress of the Association was satisfactory. The number of members had increased from 4,578 to 4,648. The Association had gained considerably in strength and energy since the unhappy incidents at Cardiff. The report was adopted. The following resolution was adopted :—"That this conference is of opinion that considerable dissatisfaction still prevails in the service, and that Mr. Raikes's revision has not redressed all the grievances under which we suffered ; and that, moreover, the late scheme presents several anomalies and inequalities." An addition to the motion was adopted, on the suggestion of a Belfast delegate, to the effect that "the number and value of superior appointments in the telegraph branch should be in proportion to the number of clerks employed, and that the proportion should be equal to that enjoyed by the postal branch." The following resolution was then carried :—"That the Dublin resolution shall be rescinded, and that the commencing salary of the general body of provincial telegraphists shall be as at present fixed ; but that the classification of these officers into three classes be abolished, the entire body to consist of one class, and that the annual increment be as at present fixed, and at the end of five years' service the salary be 28s. per week, rising by 2s. 6d. per week until the *maximum* salary be reached, which should be fixed at £200 per annum." The next conference will be held in London.

Bi-Metallic Conductors.—Writing to the *Electrical Review*, of New York, with reference to the Martin bi-metallic conductor and the tests thereof made by Dr. Laisant, Prof. Moses G. Farmer remarks that these gentlemen "ought to know that, on May 30, 1865 (26 years ago), the United States Patent Office granted and issued a patent to Moses G. Farmer and George F. Millekin for a copper conductor having a core or covering of iron or steel. Neither do they seem to know that a half mile of such compound or bi-metallic wire was made in New York by the electro-deposition of copper upon steel in 1868. . . . Neither do they seem to be aware that an ingenious machine was invented and patented by Mr. Alanson Cary, of New York, which would draw a skelp or covering of pure copper upon and over a steel wire, which had been tinned superficially to prevent its rusting, and to aid in soldering the copper to the steel. Nor do they seem to be aware that, by the use of these machines, many hundreds—yea, thousands of miles of wire of this kind were made, put up, and used. . . . Neither do they seem to be aware that a line of telegraph was erected in New Hampshire, in length more than 25 miles, which is still in use. . . . MM. Martin and Laisant seem not to be aware that a wire, which was over $\frac{5}{8}$ths of a mile in length, was stretched across the Mississippi River in 1870, and that it did good service for many months. Also a wire of over 1,200 feet in length did service at the Dudley Observatory for a long time. They do not seem to know that in the earlier eighties many miles of compound, or, if you like it better, bi-metallic wire, were manufactured by the Postal Telegraph Company, working under the patent of the late Luther L. Smith. MM. Martin and Laisant seem not to be aware that about 1,000 miles of this electrolytically deposited wire of sufficient size to offer only one and a-half ohms per mile of resistance were erected between New York and Chicago some dozen years ago, and that communication by telephone was held by means of this wire between the two cities. . . . ."

MAGNETISM IN IRON AND OTHER METALS.*—XLII.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 125.*)

§ 146. **Tractive Force in Divided Magnets.**—The remarks which have been made in the preceding paragraph may fitly be followed up by a reference to the attraction which subsists between two portions of a magnet when, instead of an imaginary plane of section, we have an actual surface of separation. Let a ring or long bar magnet be cut into portions which have their ends carefully faced to be true planes, and let these abut against one another. The force between the faces may be determined by measuring the amount of pull which is required to draw them asunder.

Measurements of the tractive force between the parts of a divided magnet were made by Joule,† who showed that the amount of the force required to separate two parts of a divided magnet varied as the area of cross-section, and found that the tractive force might be as great as 175lb. per square inch. Shelford Bidwell,‡ using a divided ring electro-magnet of iron,

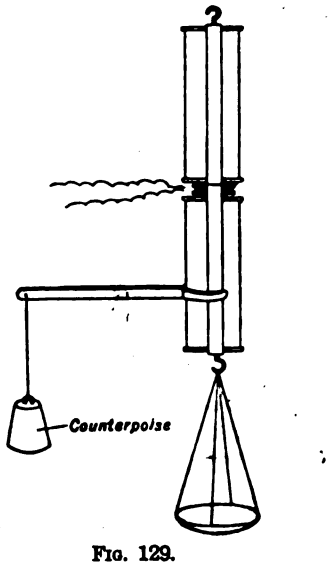

Fig. 129.

found that the weight which could be sustained per square centimetre of the cross-section was related to the magnetising force in the manner shown by Table XXV. :—

Table XXV.—*Tractive Force of a Divided Ring Electro-Magnet.*

Magnetic Force H.	Tractive force in grammes weight per square cm.	Magnetic Force H.	Tractive force in grammes weight per square cm.
3·9	2,210	145	12,800
5·7	3,460	208	13,810
10·3	5,400	293	14,350
17·7	7,530	362	14,740
22·2	8,440	427	15,130
30·2	9,215	465	15,275
40	9,680	503	15,365
78	11,550	557	15,600
115	12,170	585	15,905

As one gramme per square centimetre corresponds to 0·001421b. per square inch, the highest tractive force reached in this experiment was 2261b. per square inch. In these experiments the values of the magnetisation were not directly observed. They may, however, be inferred from the values of the tractive force in a manner which will be explained presently.

Further experiments on the same subject have been made by Bosanquet§, who used bar magnets, and employed a small induction coil (encircling the bar close to the surface of division) to determine the value there of B at the instant the two portions of the bar parted company (Fig. 129). In this case it was possible to compare the actual tractive forces with the values which the forces which were to be anticipated from the known values of B. Bosanquet has made this comparison, and has found a fair agreement except in the early stages of the experiment. When B had any value less than about 5,000 the observed tractive force was greater than the calculated force. This is possibly to be ascribed in part to friction in the appliance by which the lower magnet was guided, and in part to a supplementary attraction between the magnetising coils, which was then more considerable than when B was greater. With an induction B of 18,500 Bosanquet observed a tractive force equivalent to 2071b. weight per square inch of section of his iron core.

§ 147. **Relation of Tractive Force to Magnetisation.**—In connection with these experiments it is interesting to inquire what is the relation that theory would lead us to anticipate between the magnetisation of the core of a rod or ring electro-magnet, and the tractive force necessary to overcome magnetic attraction at the abutting forces if the core is cut in two. This matter has been the subject of some discussion,* and it appears to the writer that a sufficiently careful distinction has not always been drawn between different conditions which, to some extent, affect the result. Consider the case of an indefinitely long rod, or a ring, wound throughout with a solenoid which produces a uniform magnetic force H. Let the intensity of magnetisation be I and the induction B, as usual. Let the rod or ring be cut across, the cut faces be scraped to form true planes, and placed in contact, so that the whole behaves, magnetically, as nearly as possible like an undivided core. At the junction there is an indefinitely narrow crevasse, on each side of which the surface density of magnetism is I. The result of that is (as was shown above in § 145) that the opposing surfaces pull one another together with a stress the amount of which per square centimetre of surface is $2\pi I^2$ in dynes. Since $B = 4\pi I + H$ this quantity may be written $\frac{(B-H)^2}{8\pi}$. If the magnetism that is dealt with is residual (that is to say, if H is zero) this is the whole force that must be overcome in separating the surfaces. So that if s is the area of surface in contact the whole tractive force is in that case equal to $2\pi I^2 s$. But suppose H is not equal to zero, in other words, suppose that some current is circulating in the solenoid, then the separation of the opposing forces involves the movement through a field H in the direction of the field, of a quantity of free magnetism, the amount of which (per centimetre of surface) is I. There is, therefore, a supplementary force required, the value of which is H I.

But this is not necessarily all. The solenoid may itself be wound in two portions—one on each part of the divided core—so that the separation of the core involves the separation of the two parts of the solenoid. In that case we have to exert enough additional tractive force to overcome the attraction of one coil on the other. The amount of the attraction will depend on the area of the coils. Take the simplest possible case, that of a solenoid so closely wound upon the core that the area of the coil may be considered identical with the area of the core. The two coils, considered alone, then behave like magnets having poles whose surface density is $n c$, where n is the number of turns per centimetre, and c is the current. The attraction between them, per sq. cm., is, therefore, $2\pi n^2 c^2$. Since H is equal to $4\pi n c$, this attraction may be written $\frac{H^2}{8\pi}$. We have here a third term which has to be added to the other two in the case considered, namely, when the solenoid (closely wound on the core) is parted along with the core. It must be borne in mind that the second term H I occurs in this case, as well as in the case where the solenoid remains undivided, and the two parts of the core alone part company. For in the case of a divided solenoid each half of the solenoid pulls the opposing half core with a force which, per unit of area, is $2\pi n c$ I, or $\frac{1}{2}$ H I. There are two such forces to be overcome, namely, between the lower core and the upper solenoid, and between the lower solenoid and the upper core, and the two make up H I as before.

Digitized by Google

In the case, then, of a divided electro-magnet, in which the magnetising coil parts along with the core, and in which the coil has no superfluous area (which would add still further to the tractive force), the whole force is made up of three parts— $2\pi I^2 + HI + \frac{H^2}{8\pi}$.

This may be written

$$\frac{1}{8\pi}(16\pi I^2 + 8\pi HI + H^2)$$

$$= \frac{1}{8\pi}(4\pi I + H)^2 = \frac{B^2}{8\pi}.$$

This is the formula commonly used in calculating the relation of the tractive force at the cut to the magnetism. In the exact consideration, however, of any given case, the particular disposition of the magnetising coil should be taken account of. If it is in one length, or carried independently of the core, so that the pull of its two parts on one another does not have to be overcome, the tractive force is less. If, on the other hand, the coil is separated along with the core, and has an area larger than the core itself, the force to be overcome expressed per centimetre of the core will be even greater than $\frac{B^2}{8\pi}$. In practice, especially when dealing with iron, the term expressing the mutual attraction of the magnetising coils is generally insignificantly small, since B is enormous compared with H, for such values of magnetic force as are usually employed.

By considering on general principles the state of stress in a magnetic medium which would give rise to the mechanical forces that are observed, Maxwell* showed that where there is no magnetisation† there is a tension along the lines of force equal to $\frac{H^2}{8\pi}$. Within the indefinitely thin crevasse of air which separates the two opposed faces of a cut magnet there is no magnetisation, and the value of H there is that of B in the substance of the metal. This expression for the tractive force between the faces is therefore equivalent to the expression which has been deduced above in a more elementary fashion, namely, $\frac{B^2}{8\pi}$

§ 148. Determination of Magnetisation by Measuring the Tractive Force.—Once a relationship is established between the tractive force and B or I, measurements of the tractive force may be resorted to as a means of determining magnetisation. This gives a fourth type of magnetic measurements, distinct from the ballistic, the direct magnetometric, and the optical methods which have been described in earlier chapters. The traction method of determining magnetisation has been used with good effect by Bidwell, who determined curves of magnetisation by observing the relation of the tractive force required to separate the halves of a divided iron ring to the intensity of magnetising force produced by a divided solenoid with which the halves of the ring were wound.‡ In reducing the results he used $2\pi I^2 + HI$ as the equivalent of the tractive force. In the actual circumstances of his experiment the addition of the third term $\frac{H^2}{8\pi}$ (making $\frac{B^2}{8\pi}$ in all) would have been proper;§ but the effect of this change on the numerical values of B or of I deduced from his experiments is quite trifling. His magnetic forces ranged up to 585, and producing at their highest value an amount of attraction from which I was calculated to be 1,530, B 19,820, and μ 33·9.‖

More recently Prof. S. P. Thompson has proposed the use of a simple traction-measuring instrument as a workshop appliance for determining permeabilities.¶ This "permeameter," as he terms it, is shown in Fig. 130. The specimen to be tested is a rod which slips through a hole in the top of a substantial iron yoke, and through a bobbin on which the magnetising coil is wound. The lower end of the sample is faced true, and rests on a part of the yoke which is also carefully surfaced. The force required to detach the sample from the surface of the yoke is measured by means of a spring balance. In consideration of the fact that the magnetising coil is left *in situ*, Prof. Thompson takes $\frac{(B-H)^2}{8\pi}$ as the quantity that represents the tractive force, and from this the practical rules are derived:—

$$\text{Pull in lbs.} = \frac{(B-H)^2 \times s \text{ (square centimetres)}}{11{,}183{,}000},$$

or, $$B = 3344\sqrt{\frac{\text{Pull in lbs.}}{s \text{ in sq. cms.}}} + H,$$

or, $$B = 1317\sqrt{\frac{\text{Pull in lbs.}}{s \text{ in sq. inches}}} + H.$$

It appears to the writer that the place chosen for the plane of contact in the "permeameter" is a rather unfortunate one,

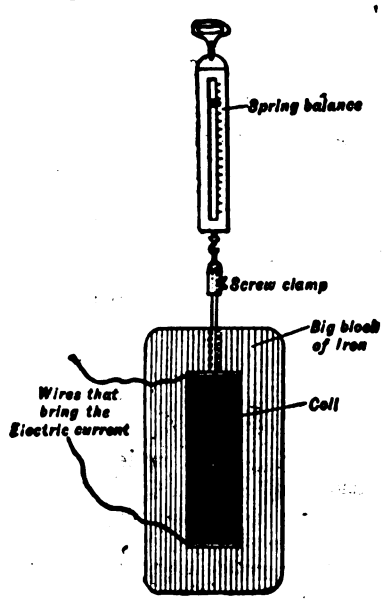

FIG. 130.—The Permeameter.

the distribution of induction being very unequal where the bar meets the yoke, and that better results might be obtained by making the sample in two pieces with a plane of contact at the middle. Apart from this, however, no traction method can be regarded as a very satisfactory means of examining the magnetic quality of a metal. The presence of tensile stress itself affects the quality which is undergoing measurement, and, as will be shown later, a divided rod or ring does not behave magnetically quite like a whole rod, even when the ends are surfaced as carefully as is practicable. The existence of a cut lessens the permeability of the piece.* The traction method is at the best inexact, but it affords a handy means of making rough and ready measurements, especially for purposes of comparison.

(To be continued.)

* Electricity and Magnetism. Vol. ii. §§ 641-646.
† Loc. cit. § 643.
‡ *Proc.* Roy. Soc., 1886, Vol. XL.
§ As Mr. Bidwell has himself remarked, *Phil. Mag.*, 1890, XXIX., p. 440.
‖ To calculate B from the tractive force F we have $B = \sqrt{8\pi F}$, F being expressed in dynes, or

$$B = \sqrt{8\pi \times 981 \times \text{Force in grammes}} = 157\sqrt{\text{Force in grammes}}.$$

This formula will serve to determine B from the values of the tractive force given in Table XXV.

ON THE ENERGY CAPABLE OF BEING STORED IN THE MATTER OF SPACE OR ETHER.

BY S. TOLVER PRESTON.

Some calculations of amounts of energy capable of being stored in the matter of space or ether under data, quite possible in practice, may be useful to aid the powers of realisation in view of the direction in which science is advancing.

This matter permeating space is supposed to move in the simplest way, viz.: the movement characterising the kinetic

* *Phil. Mag.*, Sept., 1888.

Digitized by Google

theory of gases; and this being the known constitution of the atmosphere, we have one basis of analogy to work upon. Also, as an explanation of gravitation seems to require this movement of matter, the calculations may have some actual interest, in addition to the exercise of the imaginative powers. At any rate, the results will be true, under conditions taken as a basis, which are perfectly possible in nature.

First of all, to calculate how much energy is contained in a grain of matter moving at the velocity of light.* This velocity is, we know, a measured one, of which there is no doubt. The working out of the computation, which is obviously very simple, is not appended, but the result can be readily verified, of course.

(1.) Results are as follows:—

Total energy enclosed in one grain of matter (subdivided into particles or not) moving at the speed of light, is calculably equal to 1,000,000,000 foot-tons, in round numbers.

Or it is equal to the energy possessed by an imaginary cannon ball weighing 40,000 tons, moving at the speed of 1,200 feet per second.

In other words, the work producing power contained in a grain of matter moving at the velocity of light is (calculably) capable of projecting a weight of 100,000 tons to a height of nearly two miles (1·9 miles).

(2.) If the density of the kinetic ether be taken at 1-5 millionth of an atmosphere (only), which represents a "vacuum" so extreme as to be difficult to estimate accurately; then (with a normal velocity of particles equal to that of light) the pressure of the ether would calculably be 500 tons per square inch (about).

(3.) It may be computed that one grain of ether which possesses the above density (1-5 millionth that of the atmosphere) would occupy a cubical space, with side of cube equal to 45ft. Hence (applying our above result), the ether contained in this moderate volume of space has a work-producing power capable of lifting a mass of 1,000,000 tons a height of 1,000ft., which is tantamount to raising a hundred ordinary armour-plated ships to this height (1,000ft.). This illustration is chosen merely to give an idea.

(4.) The energy enclosed in a single cubic foot of space, under these conditions, equals 10,700 foot-tons. Taking the mean velocity of *air* molecules (represented by their normal translatory motion) at 1,600ft. per second: then energy stored in a cubic foot of ether, whose mass represents $\frac{1}{21120}$ of a grain, equals energy of normal translatory motion of molecules of a quarter of a ton of air. This amount of air would occupy a cube with side equal to 41ft.; and the translatory motion of the air molecules, if utilised, would be capable of projecting the air in this cube to a height of about seven miles. So that the energy enclosed in the *air* under the accepted kinetic theory is demonstrably explosive.†

(5.) It may be computed that the energy stored in 2½ cubic feet of space (ether) equals that contained in a railway train weighing 200 tons, moving at 60 miles per hour.

(6.) If—to take another illustration—space were filled with leaden bullets which just graze each other without touching, then the velocity of the bullets (of which space is supposed to be quite full) would require to be, roughly, 1,400ft. per second, or about that, when discharged from an ordinary gun, in order that total sum of energy thus existing in this "rain of lead," so to speak, might equal the energy stored up in the ether in its normal state.

(7.) To afford an idea of relative mass of the ether, taking the above value for ether density, viz., $\frac{1}{1000000}$ of an atmosphere, we may compute that a mass of ether equal to the mass of the sun would be contained within a spherical space of radius which lies a little within Uranus' orbit. This quantity or mass of ether (if the energy of its component particles were entirely utilised) would be capable to give the sun a translatory motion equal to that of light. It would scarcely be believed, perhaps, at first sight that matter so rare as to surpass a good "vacuum," and contained well within the radial limits of the solar system, could enclose an energy competent to give the sun the speed of light, under the assumption that the normal velocity of the ether particles does not exceed this measured unit of velocity. Yet this is seen to be so.

We may calculate in the same way that the mass of ether enclosed within the spherical limits of the solar system itself (the orbit of Neptune) equals, under the above data, four times the sun's mass, *i.e.*, the quantity of matter contained in such a sphere of ether is equal to four times the quantity of matter which forms the sun.

Some might say that calculations as to amounts of energy capable of being stored in space have no definiteness, because we do not know the densities and the velocities of the matter concerned; and by assuming high enough velocity any amount of energy may be conceived stored up.

But first, the essential point to note is that, taking* a known velocity (no greater than that of light) as a basis, then it can be proved definitely that, by a density of matter not surpassing that of a very extreme "vacuum," an energy to the astonishing amount of 10,000 foot-tons can be stored in every *cubic foot* of space, and exerting a pressure of hundreds of tons per square inch. Secondly, it may easily be proved beforehand, that even if such energy did exist, stored in space as an actual physical reality, it would necessarily be concealed from our senses in its normal state; since the higher the normal speed with which particles of matter are endowed, the *less* is the resistance to the passage of objects through such matter, the *more* does the presence of such matter elude ordinary detection, therefore.

These points, with definite calculations as to amounts of energy capable of being stored up under data, by no means impossible or even unlikely in themselves, are the objects that it is sought to illustrate in the present essay.

Is Machinery Mistaken for Source?—A misprint having occurred in my article "The Ether as a Source of Motion," in *The Electrician*, of April 24th, which somewhat obscured the meaning on one point, I would say a few additional words.

It was contended that there was no necessity to wait for absolute confirmation of the (broad) view that coal and oxygen molecules approach each other by ether stresses (heat waves being already proved to be electric) in order to theorise on the system of deriving work.

If work come from the ether, the ether is the source of work obviously, and not the coal. Why has coal come to be commonly regarded as a source of power in itself? I think it must be mainly due to the fact that coal (as a *machine*) is not employed like a normal machine for driving motion from a† source of motion; but the coal is only used once and then

* The velocity of light is here taken in round numbers as 190,000 miles per second. This is a little in excess of the true value, but if the exact value had been taken it would have made no practical difference in our calculations.

† If, therefore, the motion in the atmosphere (that of its molecules) can be explosive in its energy without appealing to our senses, why should not this be possible or easy to conceive in the case of the ether? As *demonstrated* facts are always worth considering, we may further remark that if a piece of ice be held in the hand, we have no particular appreciation of the internal motion therein. But it may be readily calculated from the mechanical equivalent of heat, that the concealed tremors in a piece of ice—which throw the ether into wave motion in all directions—would, if completely utilised, be competent to project the ice to a height of more than 60 miles in opposition to gravity. The motion here imperceptible, but demonstrated to exist (by experiment) is, therefore, more than explosive; *i.e.*, no gun yet invented could project the ice to that height. It is one thing to know a fact, quite another to *realise* it. Without such realisation, the practical lesson is lost in its application to possible realities of nature.

* In order not to clash with observation, it becomes necessary to show, under a dynamical theory, that an adequate ether pressure (consistent with observed ether stresses, "magnetic," "electric," &c.) can exist, without the density of the ether being perceptible.

† It might seem almost a platitude to remark that a source of motion is a source where motion exists. Some might reason in this way at first sight. If the steam be not a source of motion but gets its motion from the coal, if the coal be not a source of motion, but obtains its motion from the ether, where does the ether get its motion from? But the ether *already has* motion in its normal state (an inexhaustible store of motion). The ether is, therefore, the only competent source of motion. But some might object—the coal has motion in its normal state, its heat vibrations. But the energy evidently cannot come from this; for if it did, the heat vibrations of the (molecules of) coal would be *diminished* in communicating motion to engine. But they are increased, on the contrary. The motion obtained cannot be at the expense of the heat vibrations of the coal, therefore; the motion must be derived from a source where motion exists and where no perceptible diminution of the supply is observed, from the fact that the store is practically inexhaustible.

Digitized by Google

rejected or thrown away. The reciprocating parts of the machine coal, I would say (or, rather, the collective machine carbon and oxygen) make one stroke and then become useless. It is not so much the question, is there a remedy in this, or in other (larger scale) cases, as a question of recognising* the fact.

It next seems curious at first sight that if the ether be the general source of motion, we can only derive motion from it by expending or rejecting a quantity of machinery proportional to the power derived. This appears an anomalous way of obtaining motion from a source. Can no normal machine for deriving motion from the ether be discovered, *i.e.*, a machine that can be kept in employ, and not be thrown away after having made one stroke?

Now, it is precisely the abnormal way of expending or rejecting machinery in obtaining power from a source (the ether) in quantity proportional to the power derived, which has given us the idea *that the power comes from the machinery itself;* and we have practically lost sight of the source altogether. This seems a truly anomalous or curious state of affairs, whether there be a† remedy or not. I would refer back to the article in question (April 24th) for the additional development of connected points, and venture to suggest that it should be read with the correction five lines from top of second column—"Coal must be regarded as a mere *machine*," instead of (misprinted) "new" *machine*.

Some may say it is too soon to go into these matters. But surely those who reject "action at a distance" can ask themselves what is the true theory of work by its rejection: or it cannot be too soon to do this. In fact, I suppose there are very few who would not now protest if a belief in "action at a distance" were attributed to them.

Prof. Rankine emphasised the notable truth that no law‡ of conservation applies to "force" in the sense of tendency to approach (called "attraction," magnetic, electric, gravitational, &c.), or to a tendency to recede—called "repulsion"—or to any tendency whatever. Conservation applies to *energy* clearly, which (unlike the above tendencies) could not be neutralised or nullified by any conceivable device. Well, one can see the immense importance, at once, or gain to us, in recognising that so-called "forces" are dynamical or material. For in spite of the fact that the neutralisation or nullifying of "force" (in the sense of tendency) by some device, would not be opposed to the conservation of energy; yet we have no control whatever over "force" in the *quasi* spiritual sense attempted to be attached to it (*i.e.*, in the sense of "action at a distance"); we must accept its sway, if once assumed to exist, as a sort of grinding necessity. But, on the other hand, when we realise that tendencies to approach, called "attractions" (or to recede, called "repulsions"), may be due to ether stresses, then we have something under our control, to a certain extent at least. We can manipulate ether, we cannot manipulate (assumed) spiritual "force," so there is no chimera in the *a priori* hope that we may be ultimately able to get work from the ether (which we *do* get now) in a more advantageous way than now, *i.e.*, without* spending work uselessly on the ether, in a manner that can serve no conceivable object whatever.

Without wishing to go into economical questions here, it may just be remarked, in passing, that possibly the keenness of the struggle for existence (in spite of the advance of science and the practical riddance of "action at a distance" by the late discoveries) may be attributed in part to the very expensive methods of deriving motion from the ether at present in use.

Some might consider the above theory of work (illustrated in the article published May 1st and that of April 24th) as very materialistic. The dispute about materialism has been shown to be a mere war of words. If it be meant that there is a show of *necessity* in the doctrine, the contrary may be sustained, for it is the notion of unalterable (spiritual) "force" which constitutes "necessity." We cannot interfere with such "force;" we can, on the other hand, make ether our slave (so to speak). If the ether, for instance, be the source † of the bodily movements, the ether does not direct us, but we direct the ether. These movements depend on the brain (and therefore on the identity or individuality of which the brain is the seat), not on the ether. The ether is no more a director or governor than the steam governs the very elaborate work turned out by some engine constructed by man. "Force," ‡ on the other hand, is the real necessity master; but, fortunately, its days may be said to be numbered in view of the late epoch-making discoveries of Hertz and others,

Ether and Matter.—The assumption of any inherent or fundamental difference between ether and ordinary matter, if gratuitous, certainly tends to check progress.

The publication of the following, written chiefly in answer to two questions, as under, although elementary, may elucidate this point.

(1.) As the ether is imponderable and without mass, how can it do mechanical work?

(2.) In what form is a foot-pound of energy during the time it takes to pass from the sun to the earth?

The reply offered was briefly as follows:—We have no evidence, and, consequently, no right to assume that the ether is essentially different from ordinary matter.

Ordinary matter has *not* the property of "ponderability," at least, we have no evidence for assuming that it has. A piece of cardboard may be said to be "ponderable" towards a vibrating tuning fork § which "attracts" the cardboard. So a portion of matter may be said to be "ponderable" towards the earth which "attracts" it. But this "ponderability" is no more an innate or inherent property of the portion of matter relatively to the earth (‖as far as all evidence goes), than "ponderability" is an inherent property of the cardboard relatively to the attracting fork. So far from there being evidence that gravitation is a "pull," all analogy goes to show that it is a thrust, *a tergo*, the only intelligible effect which can be brought under dynamics. Ponderability, in the sense of an inherent quality, being then abolished by any *dynamical* view or explanation of

* I mean recognising the fact that we are dealing with machinery here, containing within itself no power.

† If there be no remedy in the case of coal, and it would be rash to assert this prematurely, there may perhaps be (query) a resource of some kind in the case of the larger scale electrically charged and magnetic bodies, &c. At any rate, there can be no harm (but only profit) in recognising or discussing the true theory of the subject by the light of recent discoveries, and the tendencies of modern dynamics.

‡ Rankine's words are, viz.: "It is certain that no law of conservation is applicable to the *tendency of a body to change its place*, nor to any mere tendency whatsoever." This paper of Rankine's was called for partly by Faraday's expressed view that the fact of the tendency of a body to approach the earth *varying* as the square of the distance, was opposed to any assumed "conservation of force." Rankine remarks, viz.: "In the case of gravitation the quantity which varies inversely as the square of the distance between a pair of bodies is their tendency to approach each other, to which no law of conservation applies" (*Philosophical Magazine*, April, 1359). It may be observed also that the intensity of "force" (in the sense of tendency) is not constant, but may be variable according to the rate at which the movement of approach, or of recession (separation), of bodies takes place. Thus, if a keeper were pulled away from an electro-magnet at a high velocity (at all an appreciable fraction of the velocity of light), the ether would be notably condensed, as it is an ether stress, and so the "force" required to separate would be greater than under normal conditions (of slow separation). Or if the approach of the keeper were very rapid, the stress would (conversely) be diminished. Hence "force" in the sense of tendency ("attraction" or "repulsion") is a fluctuating quantity, not conserved at all, but conceivably indefinitely changeable, by a constant sum total of energy in the universe. We may observe that, rigidly speaking, reverse processes of approach and separation of bodies are never in both directions equivalent, under the condition of ether stresses, simply because the ether cannot either follow up or yield to the movement (of the body) with a velocity indefinitely great.

* Reference may be made to last article on this point in *The Electrician*, May 1st, p. 14 (also to the number of April 24th).

† The bodily movements are *known* to be derived from or to be at the expense of the oxydation of the food (chemical action). Now, molecules are electrically charged bodies, and if their "chemical" action be an ether stress, the ether is the source of the bodily movements (or the receptacle whence the energy is derived).

‡ I mean "Force" in the sense of a supposed entity which can travel without time. We have the best of reasons for believing that such an entity is a myth. It was conjectured by some only a few years ago that when an electro-magnet was "energised" suddenly, and a "keeper" lay a mile off, something took a flying leap from the magnet to the keeper at such a rate that it jumped "out of time," altogether.

§ The attraction is here, of course, due to the excess of the (normal) air pressure at the back of the cardboard, the air in front being rarefied by the vibrating prong.

‖ Reference may be allowed to my letter "On the Dynamics of Gravity," published in *The Engineer* of April 10th.

Digitized by Google

gravity, the ether becomes* like ordinary matter, possessing no more "ponderability" (*as an innate or inherent property*) than ordinary matter does. The idea that ordinary matter possesses distinctively the inherent quality of "ponderability," while, on the other hand, it is assumed that the ether does not, tends, of course, to make the ether appear an abnormal substance where analogies in the reasoning are impossible, and so a distaste for the study of the ether may arise.

As to the foot-pound of wave energy during the eight minutes it takes to pass from the sun to the earth, it would then be in the ordinary form of energy, *i.e.*, doubtless in the form of particles which possess an acceleration of some kind (much in the same way as the particles of air in a wave of sound have an acceleration). In regard to this point, a small calculation made some years ago by me may be briefly mentioned, viz., that the *wave* energy (in heat waves) in a cubic foot of ether next the sun, calculably amounts to 26·8 foot-grains.

Pressures are coming to be recognised as dynamical, generally speaking. The pressure of the air is dynamical, as we know, due to the continual impacts of its molecules. Even so apparently "statical" an affair as the image in a looking-glass is dynamical, or only kept up by the constant impacts of the waves on the surface of the glass, with their reflection to the eye. So there may be no difficulty in realising by analogy that the pressure termed "gravity" is dynamical, although it be as constant as the pressure of the air, or the image in a glass.

ON THE SPEED OF PROPAGATION OF ELECTRIC WAVES IN INSULATING FLUIDS.†

BY L. ARONS AND H. RUBENS.

In one of his first experiments on the production of electric waves, Hertz made use of a square of wire which was interrupted so as to form a sparking place at the middle point of one of its sides. By means of a wire this was connected to one of two electrodes between which an induction coil served to set up very rapid vibrations. At the sparking place small sparks continuously appeared unless the conductor to the square of wire made contact with it at the middle point of the side opposite to that at which the sparking took place. Hertz pointed out that this was an interference point. If a second side of the square was cut and a longer wire inserted between the two ends, the interference point was found to have moved towards the lengthened side; but it was brought back again to its original position by the insertion of an equal length of wire in the opposite side.

The authors adopted this arrangement as a basis, but modified it as follows:—Instead of a square two rectangles of wire, 230cm. long and 35cm. broad, were placed one above the other at a distance of 8cm. One of the corresponding long sides of each rectangle was cut, and four small metal plates, 5·5cm. square, were soldered to the four ends. Over the ends of the wire immediately against the plates were placed small glass tubes, and over these short pieces of brass tube so as to form small Leyden jars, the outer coats of which were connected crossways. From the connecting wires to each pair of coverings wires were carried to the terminals of a bolometer.

The two separate rectangles of wire were further provided with two conductors, which, however, did not lead direct to the coil, but were connected to two metal sheets 8cm. square. These sheets stood at a distance of 3 to 4 cm. from two large primary plates, exactly as in Hertz's apparatus for observing electric oscillations in a stretched wire. The free ends were provided with sliding contacts attached to a vertical wooden rod, and could, therefore, simultaneously be brought into contact with various points along the longer sides of the two rectangles, at positions shown on a horizontal scale.

Since the electric oscillations were now not produced in the wires themselves, but in the space lying between the two rectangles, so that the wires determined only the directions of the waves, the length was altered if some other medium instead of air was placed in this space. The alteration in this length could be determined by the shifting of the interference point, the relation between the length for any particular medium and that for air giving the index of refraction.

One short side of the double rectangle was accordingly placed in a box and insulated therefrom with india-rubber, and carried across in one case in a straight line, and secondly in a zigzag fashion. If p_1 represents the distance of the interference point from zero when the box contained air only and the straight wire was used, p_2 that when the zigzag wire was thrown in instead of the straight one, p_3 and p_4 the corresponding distances when the box was filled with an insulating fluid whose index of refraction was n, we have

$$n \frac{p_4 - p_3}{p_2 - p_1}.$$

In this way the indices of refraction for four fluids were found to be as follows:—

Castor oil	$n = 2·05$
Olive oil	$n = 1·71$
Xylol	$n = 1·50$
Petroleum	$n = 1·40$

The dielectric constants μ for these fluids were also measured by Schiller's method. According to Maxwell $n^2 = \mu$. The results of our measurements were thus:

	μ	$\sqrt{\mu}$	n	Optical index of refraction.
Castor oil	4·67	2·16	2·05	1·48
Olive oil	3·08	1·76	1·71	1·47
Xylol	2·35	1·53	1·50	1·49
Petroleum	2·06	1·44	1·40	1·45

The values found for $\sqrt{\mu}$ and n correspond very well, though they only agree with the optical index of refraction (the D line) in the case of the last two.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

FRIDAY, June 12th.

PHYSICAL SOCIETY OF LONDON.

5 p.m. Papers to be read: (1). "Alternate Current and Potential Difference Analogies in the Methods of Measuring Power." By Prof. W. E. Ayrton and Dr. W. E. Sumpner. (2). "A Clock for Pointing out the Direction of the Earth's Orbital Motion in the Ether." By Prof. O. Lodge, F.R.S. (3). "Some Experiments with Leyden Jars." By Prof. O. Lodge, F.R.S. (4). "The Construction of Non-Inductive Resistances." By Prof. W. E. Ayrton, F.R.S., and T. Mather.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "The Rate of Explosion in Gases." By Prof. Harold Dixon, F.R.S.

WEDNESDAY, June 17th.

ROYAL INSTITUTION.

4 p.m. Faraday Commemoration Lecture. By Lord Rayleigh, F.R.S.

ROYAL METEOROLOGICAL SOCIETY.

7 p.m. Amongst the Papers to be read is the following: "A curious case of Damage by Lightning." By Alfred Hands, F.R.Met.Soc.

ROYAL MICROSCOPICAL SOCIETY.

8 p.m. Ordinary Meeting.

ROYAL SOCIETY.

9 p.m. Conversazione at Burlington House.

SOCIETY OF ARTS.

9 p.m. Conversazione at South Kensington Museum.

CHEMICAL SOCIETY.

8 p.m. Ballot for New Members. Amongst the Papers to be read is the following: "The refractive power of certain Organic Compounds at different Temperatures." By Dr. W. H. Perkin, F.R.S.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

* Without there being any inherent difference in qualities, there may, of course, be dimensional differences between the ether and ordinary matter. Thus, for instance, it is quite possible that the ether may be subdivided into particles very much smaller than those constituting ordinary matter.

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing, and Printing Offices:
SALISBURY COURT, FLEET ST., LONDON, E.C.
Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*" *All Editorial letters to be addressed to the Editor.*

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from Publishing Offices as above.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

SUBSCRIPTION RATES.

The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
For Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements should be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday.*

SMALL PREPAID ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The Directory was established in 1883, and the 1891 Edition, published on the 23rd February, 1891, consists of 900 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with well-written Biographical Notices of leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1891 should be ordered at once. Price 5s., post free 5s. 9d. Abroad postage extra. Prospectuses free.

ELECTRICAL BOOKS AND PUBLICATIONS

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

"THE ELECTRICIAN" *Series at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING. Vol. I. Price 7s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Vol. I. Price 6s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

Several Further Volumes in Active Preparation.

READY JUNE 19TH, IN TWO VOLUMES.

"THE ELECTRICIAN" PRIMERS.

NOTICE.

"THE ELECTRICIAN" PRIMERS, in 2 volumes, bound in cloth (2/6, post free 2/9, each), or in paper covers (2/-, post free 2/2, each), will be ready on Friday next, the 19th June.

Full particulars and Prospectus on application to the Publisher.

THE SCIENTIFIC SOCIETIES.

The general result of the meetings of the scientific societies during the past winter has been very satisfactory, but since the most important Electrical Papers have been divided amongst several different Institutions it is rather difficult to appreciate them as a whole. The progress of electrical engineering, and, perhaps, also the advancement of electrical science, is facilitated by the numerous opportunities which are offered for the reading and discussion of Papers, and the author of any communication has a considerable choice of audiences to choose from. The proper selection of an audience determines to a considerable extent the degree of usefulness of the communication, for not unfrequently the Paper itself is but the raw material for a discussion, and the importance of the latter in so many cases exceeds that of the former, that, if no criticisms, questions, suggestions, rejoinders, explanations, or replies are forthcoming, the Paper, good as it may be, fails to be a landmark, or even an incident, in the progress of knowledge.

We do not intend to review all these Papers, and will allude only to three which the past season has produced on the distribution of electrical energy, the first by Mr. FRANK BAILEY at the Society of Arts, the second by General WEBBER at the Institution of Electrical Engineers, and the third by Mr. CROMPTON at the Institution of Civil Engineers. Nor is it our intention to discuss the relative merits of these three, for they differ so widely in their style and contents that no close comparison is possible. The first of these was, in our opinion, almost thrown away, merely because the discussion was so poor. The Paper consisted of a sketch of the various stations at work in London, so far as the author could obtain information

Digitized by Google

about them, a table embodying the chief details, and a collection of very interesting statistics, such as the ratio of maximum lamp supply to the total lamp connection, the proportion of lamps of different candle power, the cost per annum of a lamp at different efficiencies, &c. It is next to impossible to discuss such a Paper on hearing it read, and it is only when the full text and diagrams have been in the hands of members for some days previous to the meeting, that a good discussion can be expected. It happens that it is not the custom of the Society of Arts to afford that facility to its members, and in this case the diagrams were never reproduced at all. General WEBBER'S Paper dealt largely with an ingenious switching arrangement, and with hypothetical efficiencies and probable developments. The few figures from actual practice, relating to the laying of mains elicited a definite rejoinder, but the proofs of the Paper were not circulated thoroughly enough or early enough to allow of a proper study of it before the meeting, and there was a considerable difficulty in inducing members to take part in the proceedings. The third Paper was in some respects of a less practical character than either of those to which we have referred, if the proportion between record of facts and of calculations be considered; but, in accordance with the usual practice of the Institution of Civil Engineers, it had been printed in neat pamphlet form with all the illustrations, and had been sent out to those members and associates who were interested in the subject, the result was that, even a day or two before the Paper was read, a sufficient number of names had been sent in to ensure a discussion extending over two evenings, and, as it turned out, three meetings were devoted to an important debate.

There are some Papers, such as the one on Electric Mining Machinery, which are of so purely an engineering character that even if the authors were members of the Institution of Electrical Engineers they would not be well advised in offering their communication to that body if the older one were open to them; while, on the other hand, such Papers as those on Secondary Batteries could not well be read anywhere than before the Electrical Engineers. There is a prestige about the Institution of Civil Engineers which the younger body cannot expect to rival for many a year, and there is a dignity and deliberation about its proceedings which is worthy of imitation. A Paper submitted to the Civil Engineers is, as in many other societies, carefully considered by the Council, and by no means accepted as a matter of course, but it has only a limited circulation in a proof form, and its publication in full is not permitted until the issue of the volume of the Proceedings. Another custom, which in some cases is a disadvantage, is probably a relic of former days, when the delivery of engineers of the old school was occasionally more full flavoured than intelligible; we refer to the reading of all Papers by the secretary. But these drawbacks are amply compensated by the thorough and liberal manner in which the proofs are sent round, in ample time to allow of a careful perusal of the Paper before the meeting. It is, indeed, possible that the comparative feebleness of the discussions at the Electrical Engineers is due chiefly to the absence of such proofs, or to the irregular and spasmodic manner in which they appear; sometimes without illustrations, or occasionally as a sheet of diagrams with no text. The authors may be to blame for this, but none the less it marks a very important dissimilarity between the two Institutions, and is thoroughly characteristic of the difference between them.

Discussion after a Friday evening discourse at the Royal Institution would be as out of place as at the close of a sermon, and, in many cases, to read a printed copy of the lecture first would rob the hearing of half its charm. But we do not go in for charm at Great George-street, and are content with dry facts. With rare exceptions the facts contained in a Paper, particularly if they are of a solid character, can only be appreciated by quiet study. The reading of such a Paper is a mere matter of form, as is the reading of a Bill before Parliament. The printed copy and the debate are the real matters of importance. The chief advantage offered by the Institution of Electrical Engineers to the authors of the Papers which are presented to it seems to be that the technical press are allowed to reprint the communications in full, if they please, and thus a very wide publicity is given to their contents. In view, therefore, of the utter futility of actually reading the many tabular and mathematical Papers presented, the question naturally presents itself whether, under the circumstances, the reading could not be dispensed with. The author might make a short statement before the opening of the discussion, as is always done at the Civil Engineers; much time, in fact, a whole evening would generally be saved, and a good deal more could be got through in a session. The idea is, perhaps, rather revolutionary, but the conservatism and venerable traditions of the Civil Engineers need have no counterpart in the younger and rather erratic society, which can as easily change its method of procedure as it can alter its name or its habitat. The want of point and frequent dulness of the discussions at the Electrical Engineers seems to arise chiefly from the fact that the mere reading of the Paper, especially if it be an elaborate one, does not put the audience in full possession of its contents, and a discussion started immediately afterwards on the strength of what a few favourably situated members may have heard here and there can very rarely deal with the subject in a useful way.

Defective procedure notwithstanding, the scientific societies and their meetings play a very important part in the development of our knowledge both of electrical engineering and of electrical science. The electrical papers which have been read during the past winter before the Royal Society, the Institution of Civil Engineers, the Institution of Electrical Engineers, the Society of Arts, the Physical Society, and the Society of Chemical Industry, besides the Junior Engineering Society and the Old Students' Association, contain the results of a very large amount of work gratuitously performed by some of the best men of the day, and we may be sure that they will have plenty more to offer when next winter comes round, and they may even find in the meantime something to spare for the advancement of the British Association and its science.

REVIEWS.

Wire: its Manufacture and Uses. By J. BUCKNALL SMITH. Offices of *Engineering*, London. 1891.

One might at first be surprised to find a handsome book of nearly 350 pages devoted entirely to wire, but an examination of the contents shows what a wide subject the author has attempted to deal with. The introductory chapter goes back to 1700 B.C., and, after a brief sketch of the history of wire-drawing, gives a very interesting popular account of some of the innumerable uses to which various kinds of wire are applied. Four chapters in the first section on the manufacture and uses of wire deal with the various kinds of iron and steel, their preparation, physical characteristics, and analyses. An account is given of the different methods of rolling rods, and of drawing the rods into wire, and the various precautions, such as lubrication and annealing, are described very clearly,

Digitized by Google

together with the subsequent processes of tempering, galvanising, tinning and coppering. Wire testing and straightening machines are also described in the first chapter. Wires of copper, bronze, silver, &c., their properties and uses, are dealt with rather more briefly in the second chapter, and wire gauges and methods of measuring are discussed in the third.

The fourth and last chapter of the first section is devoted to electrical conductors. Considering the enormous range covered by the subject of wire generally, the space devoted to this branch is, perhaps, fairly proportioned, and the 18 pages of this chapter deal with Matthiessen's standard, resistance of various qualities of copper and iron, the effects of annealing, temperature, density, impurities, &c., on resistance and on sag of telegraph lines. Specifications for telegraph wire, tables of weights, &c., are given, together with a description of the tests made by the Post Office authorities. The second section, on "worked wire, and its applications," is chiefly devoted to the construction and uses of wire ropes, a considerable space being devoted to haulage and mining work. It is hardly possible that this work, which concludes with chapters on wire netting, fencing, and nail making, can thoroughly interest any one individual, but engineers of every branch will find something that concerns them, and probably something that is new to them, in this excellently illustrated and well got up volume.

The Rise and Extension of Submarine Telegraphy. By WILLOUGHBY SMITH. (J. S. Virtue and Co., London. 1891.)

This book is well described in the preface as consisting of jottings set down in chronological order, where possible, of many of the incidents in connection with submarine telegraphy which have come within the personal experience of the author. It has not been his intention to write a complete history of the subject, but in the present volume many interesting details will be found by some future historian, who, while dealing with the subject from a wider and, perhaps, more impartial point of view, must needs make use of such personal experiences as these in compiling a comprehensive treatise on the subject. The manufacture and laying of the first French cable, consisting of 25 knots of No. 14 B.W.G., covered to half an inch with gutta-percha, is given in considerable detail, and the difficulties met with in the construction of numerous important cables are described, and details of several specifications and tests are given. An appendix contains reproductions of "*The Atlantic Telegraph*" issued on board the Great Eastern during the laying of the second Atlantic cable.

Smith's Tables and Memoranda for Mechanics, Engineers, &c. London: Crosby Lockwood and Son. 1891.

This little pocket-book, which has reached its fifth edition, would have been noticed before, but it is so small that it was actually lost in a pocket for a week or so. Although "revised and enlarged," it weighs only a trifle over an ounce. The 16 pages devoted to electrical matters need a little more revision here and there, *e.g.*, it is suggested that there is a Board of Trade rule imposing a limit of 2,000 amperes per square inch. The remaining 242 pages are full of tables that are very useful to engineers. The last two sections are devoted to "Useful suggestions in cases of accident or illness," and to "Knots and splices."

ELECTRIC AND MAGNETIC THEORIES.

BY SILVANUS P. THOMPSON, F.R.S.

(*Concluded from page 133.*)

§ 18. Mr. Sprague has so frankly committed himself to the doctrine that the electric current is propagated in the conducting wire, as water is in a pipe, by end-forces acting longitudinally, that it would seem hopeless to expect him to relinquish his views on this point, however untenable they may prove to be. Before he finally settles himself down into the acceptance of his own views, he must, however, get rid of one most unsettling fact, unsettling that is for those who do not yet grasp the significance of Hertz's experiments, nor comprehend the part played by the medium in the propagation of electric actions. I have already hinted at this fact; I now put it forward as a cardinal point in the controversy. The stream-lines of the flow of an electric current where it spreads out in a sheet or ribbon, and flows past and around some non-conducting obstacle, are of a form wholly distinct from the stream lines of an ordinary fluid propelled past an obstacle of similar shape. Fig. 15 represents the form of the stream lines of an electric current flowing in a strip of tinfoil across the middle of which a small cross-cut has been made as an obstacle. The form of the stream-lines can be experimentally found by first ascertaining, by means of a sensitive galvanometer and a couple of exploring pins connected thereto, the positions of the equipotential lines across the strip; and then drawing the stream lines so as to cross these everywhere orthogonally. It will be noticed that these electric stream lines are symmetrical in front of and behind the obstacle.

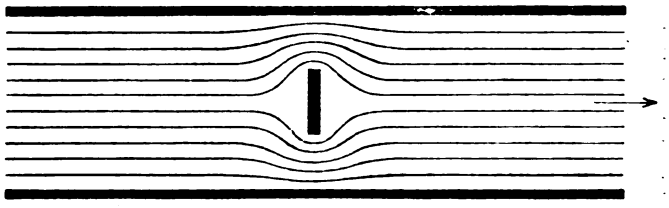

FIG. 15.

In Fig. 16 are shown the stream lines of a real fluid in a narrow channel when passing an obstacle of the same form as in the preceding case. They widen out after passing the obstacle, and set up, as they pass, a couple of swirling eddies in their trail; there being an actual back-wash toward the obstacle down the middle line between the eddies.

Now, it has been shown by Oliver Lodge in the chapter on current phenomena in his book, "Modern Views of Electricity," from which these two figures are taken, that in order to account for this difference between the stream lines of the electric current and those of an actual fluid, we are compelled to accept one of three possible alternatives.

Either (1) there is no friction in the path of the electric current; or (2) there is no inertia in the flow of the electric current; or (3) the propelling force acts at every point of the path; just enough energy arriving at each element of the path to produce in the length of that element a force just sufficient to propel the current against the friction forces existing there.

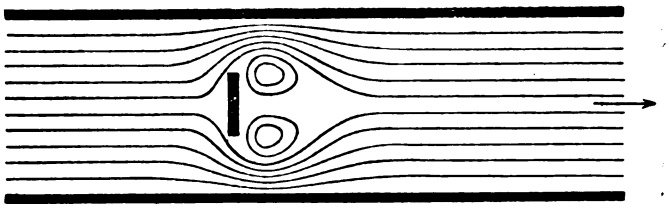

FIG. 16.

I shall be very much surprised indeed if Mr. Sprague sets up the first of these explanations as providing a way out of the difficulty, for if there is one fact on which he can lay stress on his side (and he is entirely welcome to the point) as tending to support the analogy that electricity in a wire behaves like water in a pipe, that fact is that the current heats the wire just as if there were friction in the path. I don't think, therefore, that we shall differ on this point. Secondly, if there is not inertia of the ordinary mechanical sort, there is something uncommonly like inertia in the phenomena of the extra current. It takes time to start or stop a current. It is true that whereas Mr. Sprague locates this phenomenon in the wire, I, as a follower of Maxwell, locate it in the medium outside. Its precise location is not, however, so important an affair as the question whether it exists. If it does not exist, then no argument can be drawn on the matter in question, because then the form of the stream-lines is compatible with either longitudinal end-thrust or with distributive supply of energy at every point. If it exists then the only

Digitized by Google

possible conclusion can be that the energy that propels the current is supplied distributively at all points, just as required; and not by end-thrust. If we accept Poynting's deductions from theory as to the flow of energy inwards to the wire from the medium along the intersections of the static and magnetic equipotential surfaces, at every point, as explained in §16, p. 133, then the difficulty about the stream-lines entirely disappears, and leaves the question of inertia undecided either way.

§ 19. Possibly Mr. Sprague, while unwilling to accept Poynting's view about the lateral in-flow of energy across the medium along the equipotential lines, may be prepared to jump at another solution of the difficulty discussed above, and would be ready to accept the third alternative if it could be established without involving lateral transfer of energy. If, in fact, it were possible for the energy to travel longitudinally along the conductor, and yet distribute itself just where required to propel the current against frictional or resistiag forces, he might think less unkindly of the suggestion. Let us, then, try to see what this involves. Perhaps it occurs to someone that, when water is flowing by virtue of gravity down a pipe from a high level to a low one, gravity does not act by an end-thrust exerted on the top, nor yet by an end-pull (or suction) exerted at the bottom, but pulls at each portion of the water in the pipe—in fact, acts distributively. No doubt, so far, this is true: gravity does act distributively on each portion of the water in the pipe, though not by any means in proportion to the resisting forces at every part. But even if the pipe were sloping at an angle, instead of perpendicular, gravity will act on the water inside; and the pull of the earth on the water is certainly not exerted longitudinally along the pipe, though, of course, its resultant will have

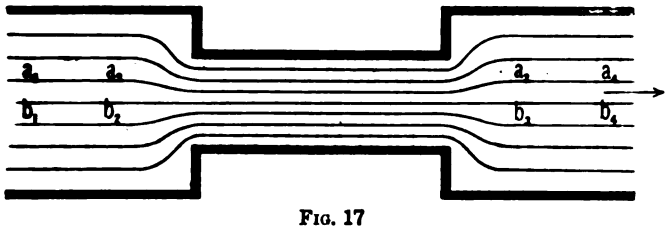

Fig. 17

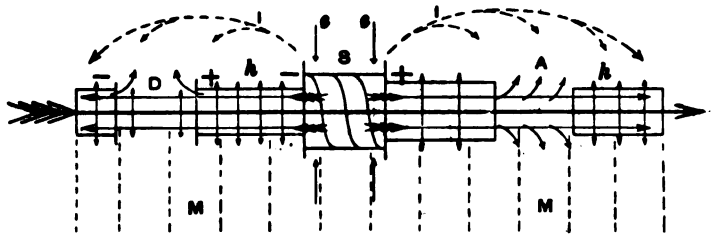
a longitudinal component. But it is clear that, if at any point the pipe is clogged, or of smaller diameter, so as to offer there a greater resistance than at other parts, gravity does not in any way concentrate itself and exert a greater pull on the water at those parts—it does not distribute itself so as to furnish energy at every point in proportion to the frictional forces at that point. Well, though gravity does not do so in the case of water in a pipe, is it inconceivable that electric forces may do so for the current along a wire? And if they do so, is this mode of action compatible with longtitudinal transfer of energy along the wire? Let us see.

§ 20. Let us consider the case of a conducting circuit of round wire, which is contracted for a portion of its length into a wire of smaller diameter. The stream-lines of an electric current in it will resemble Fig. 17; but as the flat drawing only represents what goes on in one plane, it must be remembered that the stream lines will be similarly contracted in all directions around the axis of the wire. If the thin piece of wire thus interposed be half the diameter of the thicker part, its resistance per unit of length—say per centimetre—will be four times the resistance per centimetre of the thick wire; and as the same current flows through the whole wire, the energy which is expended per centimetre in maintaining it in the thin part is four times as great as that which is expended per centimetre in the thick part. Now, consider any portion of the current in the wire lying between two of the stream-lines as seen in Fig. 17, or rather consider it in the solid rather than in the flat, as a filament of current lying within, and bounded by, a tube of stream-lines lying along its outside, like $a_1\ a_2\ a_3\ a_4$ and $b_1\ b_2\ b_3\ b_4$. The whole current may be considered as made up of such stream-filaments contiguous to one another. Now, if the current is propelled by longitudinal forces, each such stream-filament must be considered as being propelled by forces acting along its own length only, because each stream-filament is virtually independent of the others. So, if each filament is propelled by longitudinal forces acting along its own length, we have this problem to solve: How can forces propagated along the length of a stream-filament distribute themselves along the different parts of that filament in unequal amounts? It is as though we were to have a rope along which forces were being transmitted, which should pull at one part with a force of 11b., then a little further on with a force of 4lb., then, still further on, with a force of 11b. Is it not self-evident that the very way in which the forces are distributed, *unequally* along the stream filament, from point to point, excludes any notion of longitudinal propagation of the energy by a longitudinal push or pull? In facing the actual facts it becomes much more easy to understand how they can be what they are, if we suppose the energy to stream in laterally just as and where it is required, than if we suppose the energy to stream longitudinally along the wire. The difficulties in the way of this latter supposition make it impossible for us, when we consider them carefully, to hold such a view.

§ 21. Mr. Sprague has invited our attention (*The Electrician*, p. 544, March 6, 1891) to a sort of diagram, in which he embodies his views. Current being propagated by end forces longitudinally, he represents an electromotive force by a turbine which drives water into one end of a pipe of variable section, and draws it out at the other end. In this diagram Fig. 2, p. 544 (reproduced), there is some fine confused feeding for the mind. The current is represented by a long arrow from left to right, whilst the energy, which is also considered by Mr. Sprague as a sort of "current inside the conductor," is repre-



sented by four long thin arrows, two of which pass from the + pole of the turbine to the right, and two in the opposite direction from the – pole. What on earth does this mean? Does the energy flow with the current, or does it not? Am I right in taking this to mean that the current sometimes carries energy with it, and sometimes carries the energy in the opposite direction to that in which it is itself flowing? From these energy arrows there branch out sideways some smaller arrows to show how the supplies of energy "proceed" (why not "are transferred")? to carry on the work of heating the resistances and of furnishing heat and light in an arc, A, and chemical action in a voltameter, D. Frankly, I do not understand the voltameter. The current is apparently running in at its negative pole and out at its positive pole, as it would do if it were a battery. It is helping to drive the current, not exercising an opposing electromotive force. Perhaps this accounts for the difficulty about the energy arrows. Some little curved arrows facing inwards from the end-plates of the voltameter doubtless represent the energy spent in driving the current against the electromotive forces of polarisation at the electrodes. Similar curved arrows in the arc apparently represent energy supplied to the arc—nine-tenths of which, by the way, is liberated not in the arc itself but at the surface of its positive crater. Why the curved arrows in these two cases should branch out from the energy arrows, and the cross arrows which represent energy spent in heating the wires should branch out from the current arrow, is an unexplained mystery. Is not the energy that heats the wires equally transferred along the energy paths, or does it only flow in the same direction as the current? Again, there are some dotted arrows, I, outside the wire to represent "the actions which occur in the 'variable period' . . . the static charge or lines of stress existing along the whole circuit and shown in what used to be called the 'tension'

Digitized by Google

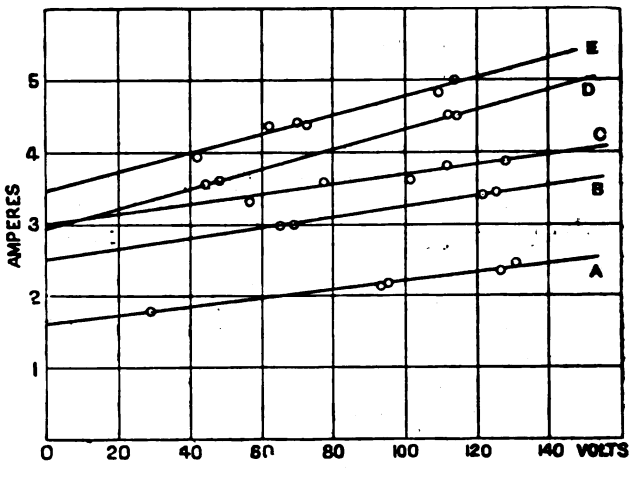
between the various parts, now called slope of potential, &c. This is what is called also the self-induction, inductance, &c." Here, then, Mr. Sprague makes it appear that lines of stress in the medium can branch out of one another—a perfectly new fact in the science, if true. Also, the lines of stress or static charge are "what is called also the self-induction!" Good gracious! what are we coming to? Mr. Sprague knows as well as I do that the slope of potential along a wire depends both on its resistance and on the current through it; and that its self-induction depends on the square of the current, and in no wise on the resistance of the wire, but only on its geometrical outline and the permeability of the surrounding medium. And yet he muddles up the two things and draws one set of arrows to represent them. Moreover, if these arrows suggest anything at all, they suggest that the energy to produce such effects during the variable period flowed from the battery through the medium—and that is not at all what Mr. Sprague is willing to admit. Indeed, he himself says: "This internal stream also supplies the energy necessary for these actions," which he is representing partly by the dotted arrows, I, and partly by the dotted lines, M. Now, if stresses, whether static or magnetic, are to be set up in the medium by energy furnished by the source, why in the name of common sense should not this energy go there direct from the battery, instead of having to run along the wire, sometimes with the current, sometimes against the current, until it comes to the proper place to stream out into the medium to set up the stress? Permit me to put the matter in Mr. Sprague's own peculiar way. How does the energy know whether it is to flow with the current or against the current? How does the energy know how far it must run along the wire before it turns outward into the medium to set up a stress? How does it know, when it gets into the medium outside the wires, in which direction and how far it has to go, and how much stress it is to set up? Or, to quote from Mr. Sprague, the query with which, on p. 576, he crushes all life out of the poor creatures who oppose his views: "How does the external energy distinguish where much or little of it is wanted?" His diagram is an absolute distortion of the facts so far as they relate to the variable period; and it is inconsistent with itself so far as it relates to the facts of the steady flow. It is safe to defy Mr. Sprague to show on any such diagram the simplest experiment of Hertz. Nay, it cannot even represent the facts of the ordinary induction coil. When Mr. Sprague goes on (on p. 609) to explain how it happens that transient currents begin at the surface of the conductor, his arguments become positively amusing. He assumes, in accordance with his Fig. 2, that the energy in the medium always runs along the conductor till it gets far enough, and then streams outwards into the medium to set up a stress. Having assumed, in order to support his views, that energy takes this roundabout way of going to its destination, he then, without proving that it does anything of the kind, goes on to say that "*because* the leakage of energy is from the conductor into outer substances in which a stress is to be set up," and because "current will only be propagated when, and so far as, all stresses are satisfied;" therefore "common sense, without the aid of mathematics, will see at once that this progressive wave of propagation must begin at the surface. . . ." I should have thought that common sense, with or without the aid of mathematics (which is only, after all, a sort of shorthand for common-sense processes of thinking and calculating), would have rather said something like this: Because energy is capable, as we know from the experiments of Hertz, and from experiments on induction coils, of setting up stresses in the medium, and of flowing along the lines of equipotential in the stressed medium, and of setting up electric currents when it arrives at a suitable conductor, and because it reaches the outside of the conductor first before it gets to the inside, therefore the current will start at the outside of the conductor before it starts inside. But no: Hertz's experiments and their logical conclusions appear to be alike thrown away on Mr. Sprague. Great as is his acquaintance with one department of electrical science, and clear as his vision is and has ever been for one set of facts—the chemical facts—he has yet to learn the lesson of the other department in which we have all had so much to learn anew. He is unfortunately under several erroneous impressions. "In fact, the distribution of energy," (he says on p. 730) "by a water current under pressure in a closed pipe, goes on under conditions *absolutely identical*" (the italics are mine) "with those of the electric current." Having said this, he then finds that he must modify the statement in order to account for the external effects in the medium, and so says "we have only to make the conductor elastic," and proceeds to substitute an india-rubber pipe for a rigid steel one. What trifling this all is. Are the copper conductors elastic? Do they swell up or contract in order to produce the effects of surface charge, external magnetic stresses, induction of currents in neighbouring wires, and the like? It is this unfortunate hydraulic analogy which dominates all Mr. Sprague's thoughts, and makes him the slave instead of the master of his arguments. If he could once grasp the real meaning of the difference between the stream lines of the electric current and those of water in a pipe, he would understand how utterly misleading is the idea that the distribution of energy in the two cases is "absolutely identical." I owe much in past years to Mr. Sprague's work; I believe him to have a single-minded desire for truth to grow; I acknowledge how justly he is looked up to by many of the younger race of electricians; I honour his services to the science in the past and in the present. All the more do I deplore his inability to see the significance of a set of facts to which he has given less mature thought; but which no student of the whole science can dare to ignore, or would wish to evade. We cannot ignore or evade the fact that, in the case of variable and periodic currents, the energy which propels the current crosses the medium and enters the conductor laterally, and does not propel the current by end-thrust. And I have shown what good reason we have in the present state of science for coming to the conclusion that in the case of steady flow, also, the energy paths are also across the medium, and not along the wire.

EXPERIMENTS ON FOUCAULT CURRENTS, &c., IN DYNAMOS.

BY R. H. HOUSMAN

The following experiments have been made to test the accuracy of the so-called assumptions on which the validity of the graphic method of analysing armature losses depends:—

Two Chamberlain and Hookham 5-kilowatt dynamos, identical in every respect, running at high speed and low induction



density in the armature (1,440 revs. and B = 12,000), were chosen, so that friction might constitute a large fraction of the total losses measured. The bearings were 1¾in. diameter at the pulley end, and 1¼in. at the commutator end; the commutators were 4in. diameter, with two pair of 1¼in. brushes on each; the armature contained about 3,400cc. of iron in the form of plates ·017in. thick, with about 10 per cent. insulation.

Digitized by Google

The two machines were coupled together by a simple flexible coupling, the friction of which was quite negligible. Then, by measuring the power supplied to machine I., the different losses in machine II. were determined by difference with fields excited and unexcited and brushes on and off. Bearing friction of machine II. was determined by difference when coupled and uncoupled to machine I., but in this case a small correction was necessary for the slight vibration caused by the two shafts not being exactly in line. The power wasted from this cause was found to be proportional to the square of the speed, and was represented by ·15 ampere at 120 volts = 18 watts. The loss due to vibration has often been noticed before, especially on a boarded floor with an armature a little out of balance.

The experiments consisted of five distinct sets of measurements—

(A) Machine I., with one pair of brushes only.
(B) Machines I. and II. coupled, only I. excited with one pair of brushes.
(C) Machines I. and II. coupled, only I. excited, four pair of brushes on.
(D) Machines I. and II. coupled, both excited, only one pair of brushes (on I.).
(E) Machines I. and II. coupled, both excited, four pair of brushes on.

It must be observed that the figures deduced for zero volts are those which would be observed if the same law held good right down to zero, as actually does hold from 120 volts to 40 volts, or from 1,440 revs. to 480 revs., which represents about the range of speed used in practice.

Brush Friction (three pairs).

From (C) – (B) at 0 volts	·52	ampere.
From (E) – (D) at 0 volts	·50	„
Mean at 0 volts	·51	„
From (C) – (B) at 120 volts	·45	„
From (E) – (D) at 120 volts	·43	„
Mean at 120 volts	·44	„

Hysteresis and Foucault Currents.

Hysteresis from (D) – (B) at 0 volts	·45	ampere.
Hysteresis from (E) – (C) at 0 volts	·45	„
Mean hysteresis	·45	„

	Amps.
Hysteresis + Foucault currents [from (D) – (B) at 120 volts]	1·22
Hysteresis + Foucault currents [from (E) – (C) at 120 volts]	1·20
Mean hysteresis + Foucault currents, at 120 volts =	1·21

∴ Foucault currents at 120 volts = 1·21 – ·45 = ·76 ampere.

Bearing Friction.

Machine II. from (B) – (A) at 0 volts	= ·88	ampere.
Machine I. from (A) – other losses at 0 volts	= 1·00	„
Mean bearing friction at 0 volts	= ·94	„
Machine II. from (B) – (A) at 120 volts – coupling = 1·06 – ·15	= ·91	„
Machine I. from (A) – other losses at 120 volts	= ·96	„
Mean bearing friction at 120 volts	= ·935	„

The figures for friction of bearings of Machine I. assume that hysteresis and Foucault currents are the same in both machines.

It appears from the above experiments that, within the limits of accuracy attainable in a shop experiment, bearing friction is constant, while brush friction *decreases* as the speed increases.

Bearing friction may be measured approximately without a second motor by running the machine to be tested as a *shunt* motor on very low volts, so that the magnets do not approach saturation. Under these circumstances, as is well known, the speed is independent of the E.M.F. at the terminals, and the power absorbed is almost constant. By calculating for hysteresis and correcting for Foucault currents from the diagram, a very close approximation for the loss in bearing friction may be obtained.

CHIMNEYS AND FLUES.*

In view of the development of heavy electrical engineering it is believed the following notes and formulæ may be found useful by a considerable number of engineers, as this somewhat important subject of chimneys does not appear to be very fully treated in many of the works mostly used in the engineering world :—

Area.

The area depends upon the amount of gases to be delivered and varies inversely as the square root of the height. If

C = weight in lbs. of coal burnt per hour,
A = actual area in square feet,
a = effective ditto,
h = height in feet,
l = length of chimney and flue in feet,
K = a constant depending on size and shape,
k = ditto ditto,
d = diameter in inches of round chimney,
s = side in inches of square chimney,
t_c = temperature Fahr. + 461° of gases in chimney,
t_a = ditto of air outside ditto,
t_{32} = ditto of air at 32° Fahr.,

then

$$a = \frac{C}{17\sqrt{h}},$$

$$A = a + k\sqrt{a},$$

$$C = (A - K\sqrt{A}) \times 17\sqrt{h},$$

$$h = \left[\frac{C}{17(A - K\sqrt{A})}\right]^2,$$

$$d = 13{\cdot}55\sqrt{a} + 4,$$

$$s = 12\sqrt{a} + 4.$$

The actual diameter or side of chimney may be taken as 4 inches greater than the effective size, as the friction of gases against sides of chimney and flue is approximately equal to a layer of air 2 inches thick, and the constants below are calculated on this basis.

K for Round Chimneys	1	feet	diameter	= ·5
„ „ „	3	„	„	= ·55
„ „ „	9	„	„	= ·59
K for square „	1	„	„	= ·55
„ „ „	3	„	„	= ·63
„ „ „	9	„	„	= ·66
k for Round „	1	„	„	= ·74
„ „ „	3	„	„	= ·62
„ „ „	9	„	„	= ·61
k for Square „	1	„	„	= ·83
„ „ „	3	„	„	= ·71
„ „ „	9	„	„	= ·68

Table *of Chimneys, giving capacity in lbs. of Coal per hour.*

Actual Diam. in feet.	Effective area in sq. ft.	Height of Chimney in feet. 60	80	100	125	150	175	200	†Side of Square in feet.

The Weight of Gases

delivered by a chimney depends upon the size of chimney and the velocity and density of gases; the velocity being reduced by the friction of gases passing through the fire, and against the sides of flues and chimney. Using the values for these losses, as found by Peclet, where

W = weight of gases delivered per second,

$$W = \cdot0807 \times A \times \frac{493}{t^c}\sqrt{\frac{64\cdot4 \times h \times (t_c - t_a)}{\left(13 + \cdot6\frac{l}{d}\right)t_a}};$$

and for chimneys over 3ft. diameter

$$W = 85\frac{A}{t_c}\sqrt{\frac{h\,(t_c - t_a)}{t_a}} \text{ approximately.}$$

Velocity of Gases.

If v = velocity of gases in feet per second,

$$v = \sqrt{\frac{64\cdot4\ h\,(t_c - t_a)}{\left(13 + \cdot6\,\frac{l}{d}\right)t_a}};$$

and for chimneys over 3ft. diameter,

$$v = 2\cdot14\sqrt{h\,\frac{t_c - t_a}{t_a}} \text{ approximately.}$$

Draught

may be expressed three ways:

1. In pounds per square foot—by the difference between the weight of a column of air of one square foot section and of equivalent height to the chimney at temperature of atmosphere, and the weight of a similar column of hot gas inside the chimney.

If P = draught or pressure in pounds per square foot,

$$P = 39\cdot8\ h\,\frac{t_c - t_a}{t_c \times t_a}.$$

2. In feet of hot gas, or the height in feet by which a column of hot gas of equivalent weight at atmospheric pressure to a column of air at temperature of atmosphere exceeds the height of a column of air of the height of the chimney.

If h = height of chimney,
h_g = height of column of hot gas of equivalent weight at atmospheric pressure,
H = draught in feet of hot gas.

$$H = h_g - h$$
$$= h\,\frac{t_c - t_a}{t_a}.$$

3. In inches of water, by the height of a column of water of equivalent pressure to the pressure P as expressed above.

If H_w = pressure in inches of water,

$$H_w = 7\cdot6\ h \times \frac{t_c - t_a}{t_c \times t_a}.$$

The height of chimney required for a given draught in inches of water is

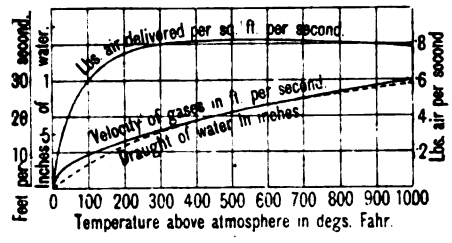
$$h = \frac{H_w}{7\cdot6} \times \frac{t_c \times t_a}{t_c - t_a}$$

$= H_w \times 134$ if temp. of gases is 550° above atmosphere,
$= H_w \times 191$ if temp. of gases is 300° above atmosphere.

The curve given on next column shows the relation between draught, capacity, and velocity of gases in chimneys, from which it will be observed that the capacity is greatest at about 600° F., *i.e.*, between the melting points of lead (630° F.) and bismuth (518° F.). The quantity of air discharged, however, at 600° is only about 4% greater than that at 300° above atmosphere, so that it is desirable where possible to reduce the temperature of the chimney gases by utilising the heat to the lower limit or thereabouts.

The draught giving best results varies with the nature of the fuel used; wood requires least, while slack or fine coal requires most draught. Generally speaking, chimneys should be at least 100ft. high if inferior coal is to be used, though 80ft. or even 60ft. may often be sufficient, where steps are taken for prevention of smoke, or where the settlement of soot in the immediate neighbourhood is not objectionable, and where fairly good coal is used.

The draught varies with the force and direction of the wind and the barometric pressure of the atmosphere, and is regulated by the damper or ashpit door.



Flues should be at least as large as the area of the chimney, and the branch flues should be of at least proportionate effective area, with 2in. added on each side all round for friction. For great lengths of flues it is necessary to increase the size of the chimney either in height or area. For lengths up to 100ft. the loss is practically negligible.

Brick chimneys are far more durable than iron chimneys. The taper, or slope, of a brick chimney should be from $\frac{1}{8}$ to $\frac{1}{4}$in. to the foot on each side. Generally for chimneys over 5ft. internal diameter they should be 1½ bricks thick at top, increasing ½ brick each 25ft. downwards.

Under 5ft. and above 3ft. internal diameter the top should be one brick thick, increasing ½ brick each 25ft. downwards.

Under 3ft. internal diameter the top may be ½ brick for 10ft. from the top, increasing ½ brick each 25ft. downwards after the first 10ft.; though 1 brick at top is always better.

The inside should be lined with firebrick 4½ inches thick to a height of about 15ft. from bottom, an air-space of 1 inch being allowed between the firebrick and main wall of chimney.

A manhole should be constructed either in the base of the chimney or in the flues for admission to the inside. It is better in the chimney, where an arched opening is made which is easily bricked up after using.

Flues should be lined with 4½ inches of firebrick and constructed with as few bends as possible, while sudden alterations in the shape thereof should be avoided. Turns or corners which are unavoidable should be well rounded. Where two flues enter a larger one opposite to each other, unless at an acute angle, there should be in the middle of the larger flue, between the two branch flues, a division or baffle plate or brick wall to obviate the formation of eddy currents. This applies also to chimneys where flues enter the base at opposite sides.

Stability of Chimneys

to withstand wind-pressure varies with the shape of the chimney, together with locality. Messrs. Babcock and Wilcox use the following formulæ:—

If W = weight of chimney in lbs.,*
d = average external breadth in feet,
h = height in feet,
b = breadth of base in feet,
C = constant,

$$b = C\frac{d\,h^2}{W},$$

$$W = C\frac{d\,h^2}{b};$$

where C for square chimneys = 56,
„ octagonal = 35,
„ round = 28.

Hence for the same weight and stability a square chimney requires twice as large a base as a round one. Or for a given base the square chimney requires twice the weight of brickwork for stability. Square chimneys, however, are more durable and less apt to crack than round chimneys.

Roughly speaking, the external diameter of a chimney at the base should be one-tenth of the height.

Iron chimneys should not be less than $\frac{3}{16}$in. thick, and for durability, with most kinds of fuel, double this thickness is

* Brickwork weighs from 100 to 130lbs. per cubic foot.

Digitized by Google

preferable. They should be continually painted to protect from rust outside. If lined with fire-brick inside, the lasting power will be greatly increased; the sulphurous gases given off by most fuels attack iron quickly.

Iron chimneys should be either firmly bolted down at the base to a good foundation, or supported by four stays attached to an angle iron ring about one-third the height of the chimney from the top.

Foundations.

It is of utmost importance that the foundation be a good one. Much depends upon the nature of the ground. On solid rock the depth from bottom of flue should be such that the heat will not affect the rock; the depth should also be sufficient to allow for spreading of the base. Where there is no rock the excavation must be carried down to a good foundation on hard clay or sand, which is sometimes not found until 20 to 30ft. down, and occasionally even deeper. It is important, too, that the bed upon which the foundation is laid should be equally solid, or unequal settling may take place. The building should on no account be continued in frosty weather, and, according to Messrs. Bancroft, in very tall shafts the rate of building should not exceed from 2 to 2½ft. per diem, while it is preferable to build tall chimneys in two or more sections, with intervals of several months intervening. The bricks used should be of good quality and of uniform thickness, and should be well soaked before being laid. Mortar should be used in preference to cement, which is attacked by heat, for the lower part of the chimney. Cement is better for the thinner work at the top, especially if 4½in. work be used. Grouting with liquid mortar should on no account be allowed. Ordinary bricks will stand a temperature of 600° F.; above that firebrick must be used.

In tall chimneys the bond should be carefully studied, and it is advisable to have three or four courses of stretchers to one of headers. To obtain additional bond, hoop iron is often built in every few courses. And for chimneys showing signs of weakness, wrought iron straps fixed at intervals round the chimney outside are often used for strengthening.

Chimneys should not be connected with other buildings, and the base of the shaft should be solid to the top of the footings, which should spread on all sides to a projection equal to the thickness of the walls at the base. Fire-brick linings should be independent of the main brickwork.

The Rules of the London County Council require—

Base of square chimneys must be at least one-tenth of the height.
„ octagonal do. one-eleventh do.
„ round do. one-twelfth do.

The batter must be 2½ inches in every 10 feet.

Brickwork not less than 8½ inches thick from top to 20 feet downwards increasing by 4½ inches at least for every 20 feet down.

In many towns in England no chimneys are allowed of a less height than 90 feet.

THE CHEMISTRY OF THE SECONDARY CELL.—A RETROSPECT.

BY G. H. ROBERTSON.

In dealing with the subject of the chemistry of cells of the Planté type, one is struck with how little advance has been made since Messrs. Gladstone and Tribe published their work on the subject in 1882. Then the questions under discussion were local action, the cause of the evolution of gas sometimes observed on first breaking the charging current, the high initial E.M.F., the resuscitating power of the cell—all problems which had been raised by Planté in his "Recherches sur l'Electricité"—and the reducibility of lead sulphate. Turning to recent work, we see nearly the same difficulties still presenting themselves for solution, and, in addition, the question of the temperature changes occurring in the cell has been raised.

Messrs. Gladstone and Tribe found that the sulphating of the peroxide plate due to local action was necessary to the action of the cell, as without it the charge would not be retained long enough to be practically available, and they also pointed out that local action increased with increase of temperature. With reference to the escape of gas, which Planté had attributed to the decomposition of water by local action, they point out that the explanation of local action given by them does not account for the escape of any gas, that the escape of gas is slight and soon ceases, but becomes more pronounced on raising the temperature of the liquid. The gas is oxygen, and heating electrolytic peroxide apart from the lead plate produces an evolution of oxygen, and they further state that testing the liquid between the plates they have always found traces of something which might be ozone or hydrogen peroxide.

Now Planté ("Recherches sur l'Electricité, § 66) noticed the formation of ozone, and observes that a lead voltameter was more favourable to its formation than a platinum, and in §74 he notes the presence of hydrogen dioxide and similar bodies in the acid, and ascribes the high initial E.M.F. to their influence, pointing out that as they are very unstable they are immediately reduced, and unless the discharge takes place at once they will have disappeared. Both Planté (§ 68) and Messrs. Gladstone and Tribe (p. 27) notice the formation of peroxide of lead on the lead plate during discharge, and that a high rate of discharge is favourable to its formation. With reference to its formation, the latter say:—"It is more easy to imagine the peroxide results from the oxidation of the sulphate of lead already formed through the agency of electrolytic oxygen. Hence we get running down of the cell before the peroxide on the peroxide plate is exhausted. On the peroxide plate the peroxide of lead being mixed with a great deal of lead sulphate will suffer decomposition only very slowly through the agency of the supporting plate; but on the lead plate the peroxide is mixed not only with sulphate of lead, but with spongy metallic lead, and will be speedily reduced to sulphate. Hence after rest an apparently run-down cell is found active." In connection with this theory put forward by Messrs. Gladstone and Tribe in 1882, it is interesting to notice the curves exhibited by Mr. Crompton at the Institution of Electrical Engineers in November last (see *The Electrician*, Vol. XXVI., December 12, 1890, p. 175), which show clearly that the higher the rate of discharge the earlier the apparent exhaustion of the cell takes place.

In March, 1883, Frankland (*Proc.* Roy. Soc., Vol. XXXV., pp. 67-70) showed that the occlusion of oxygen and hydrogen had little or nothing to do with the action of the cells, that the state of charge or discharge could be readily estimated by the use of the hydrometer, and put forward the theory that the acid concerned in the interactions occurring in the cell was Bourgoin's* hexabasic sulphuric acid. In the same year, Mr. Preece (*Proc.* Roy. Soc., Vol. XXXV., p. 250) showed that the E.M.F. remains practically constant for all degrees of temperature up to 100°C, but that the internal resistance diminishes as the temperature increases at a very steady rate, increasing again as the temperature is lowered.

Since these early discussions we have had the Paper "On Reversible Lead Batteries," by Mr. Desmond FitzGerald, read at the Institution of Electrical Engineers, March 10, 1887, which dealt chiefly with lithanode cells; Frankland's Paper (*Proc.* Roy. Soc., 1889, 46); and in reply to it Messrs. Gladstone and Hibbert's two Papers (*Phil. Mag.*, August, 1890; January, 1891). Also the two Papers, "The Working Efficiency of Secondary Cells," by Prof. W. E. Ayrton, F.R.S., C. G. Lamb, E. W. Smith, and W. Woods; and "The Chemical Action of Secondary Cells," by Prof. W. E. Ayrton, F.R.S., C. G. Lamb, and E. W. Smith, read before the Institute of Electrical Engineers last year.

Mr. FitzGerald made experiments illustrating the effect lead sulphate has in lowering the E.M.F. of peroxide of lead by mere admixture with it; and in the discussion on the Paper, Prof. S. P. Thompson dealt with a number of the hypotheses, which have been put forward from time to time, as to the chemical reactions occurring in the cell, and working out the E.M.F. of each from the thermal values given by Tscheltzow (*Comptes Rendus*, Vol. C., p. 1,458), showed which were untenable. Frankland's experiments led him to the conclusion that the lead sulphate ordinarily formed in a secondary cell could not be the common irreducible white sulphate hitherto known to chemists, because the active material always remained coloured, even

* Bourgoin, *Comptes Rendus*, Vol. LXIX., p. 890.

Digitized by Google

after discharge, and because whenever white sulphate was produced through abnormal reactions, it was with difficulty decomposed. He also concluded that the sudden fall in E.M.F. which takes place towards the end of discharge must proceed from some alteration in the chemical reactions to which the E.M.F. of the cell is due. Frankland therefore tested the action of dilute sulphuric acid on litharge and minium, and obtained bodies of the composition $(SO_3)_3$, PbO_5, and $S_3Pb_3O_{10}$ respectively, which he assumed were oxysulphates, and that their formation took place in the cell, and accounted for the sudden alteration in the E.M.F. In their first Paper Messrs. Gladstone and Hibbert dealt with the body formed by the action of dilute sulphuric acid on litharge, with the action of sodium sulphate in preventing sulphating, and with the question of the high initial E.M.F. of the cell, which they ascribe to the action of the more concentrated action formed during charge in the peroxide plate. In their second Paper they deal with the action of dilute sulphuric acid on minium, and add a note on the action of acid containing sodium sulphate when left in contact with lead for a long time. In neither case did Messrs. Gladstone and Hibbert find any ground for assuming the substance formed by the action of dilute sulphuric acid on litharge or minium respectively to be other than a mixture, but as they made use of analysis their work is open to the objection that they may have destroyed the compound. The other work and the discussion it has given rise to is so recent that it need not be further alluded to, except to say that it is in "The Efficiency of Secondary Cells" that the question of the temperature changes occurring in the cell is raised.

On reviewing the work done in this country since the publication of "The Chemistry of Secondary Batteries," we see that it deals principally with the chemistry of the plates or with physical measurements, and although there have been discussions as to the effect of sodium sulphate there does not appear to have been any attempt made to determine the character of the reactions occurring in the electrolyte itself, though the formation of peroxide bodies in the acid was noticed both by Planté and Messrs. Gladstone and Tribe, and a great deal of work has been done both in this country and abroad on the electrolysis of sulphuric acid solutions.

THE LALANDE BATTERY.

In some recent communications to the Académie des Sciences and to the Société Internationale des Electriciens, M. F. de Lalande, says our Paris correspondent, detailed the various improvements resulting in increased constancy and facility of manipulation which have been made in the construction of his original zinc-caustic potash-oxide of copper cell.

The liquid employed is a 35 per cent. solution of caustic potash, and the oxide of copper plates are now made as follows:—A wet mixture of copper scale and 4 to 5 per cent. of clay is submitted to hydraulic pressure, and baked at a temperature of 600° to 700° C., or the scale may be mixed with 6 to 8 per cent. of tar, and after moulding under pressure placed in a reverberatory furnace. The oxide is in this way reduced, and the whole mass agglomerated. On exposure to the atmosphere the metallic plates oxidise again without change of shape. The plates so obtained are very strong and porous, but poorly conducting. This defect is mainly of importance when the cell first commences working, and to overcome it the agglomerate is "metallised." A layer of powdered zinc is spread over the porous plate, and the whole is plunged into slightly acid water, local action is set up, the zinc dissolves, and the surface of oxide is reduced; but, as it would re-oxidise on drying, an extremely fine film of copper is electro deposited, a large current density of short duration being employed.

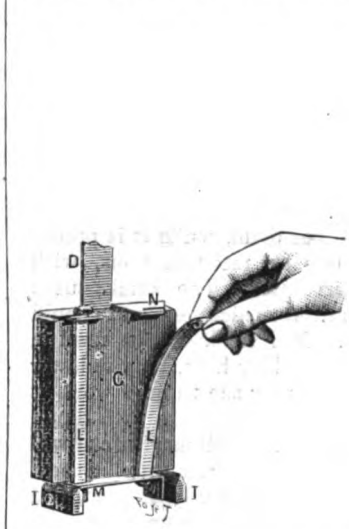


Fig. 1.—Method of mounting the Copper Oxide Agglomerate.

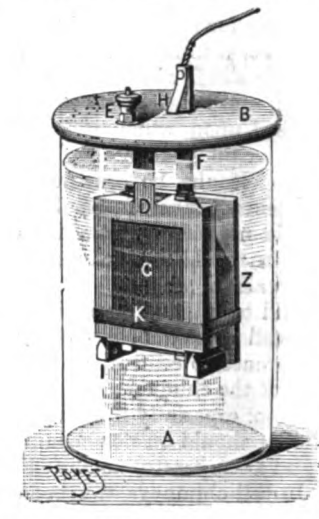

Fig. 2.—Lalande Cell (small size). C, Copper Agglomerate Plate. Z, Zinc Plate. D, Metal Support to Copper Agglomerate. B, Cover. K, Rubber Band. I I, Ebonite Insulators.

The porous plates, C (Fig. 1), are secured against sheet-iron supports, D, by means of springy strips, L L; when they have been completely transformed into metallic copper they are removed, and fresh plates inserted. The old agglomerate plates can be used again after having been washed, roasted and

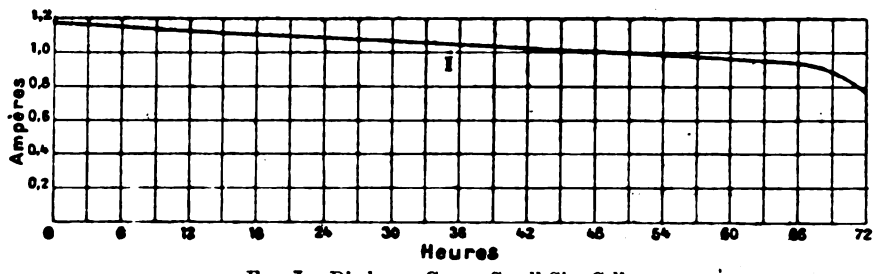

Fig. 3.—Discharge Curve, Small Size Cell.

Digitized by Google

"metallised." To prevent the zincs being attacked at the surface of the potash they are entirely submerged in it, being supported from the cover of the cell by tinned iron (Fig. 2). The zincs themselves are also tinned.

The E.M.F. of the cell on open circuit is ·94 volt, and ·8 volt under normal working conditions. Three sizes of cell are made, capable of giving 1·18, 3·25, and 6·4 amperes respectively for long periods, and 4, 12, and 25 amperes respectively for short periods. The capacities of these three sizes of cell are, respectively, 75, 300, and 600 ampere hours, and their average internal resistances ·28, ·07, and ·038 ohm. The discharge curves (Figs. 3 and 4) show the remarkable constancy of this cell.

ANALYSIS OF THE TEMPERATURE COEFFICIENT OF A BATTERY.*

BY PROFESSOR H. S. CARHART.

If the temperature coefficient is a purely thermo-electric effect, then it should be susceptible of analysis by a measurement of the thermo-electric power of the two metal-liquid pairs. If, for example, the thermo-electric power of zinc—zinc sulphate and copper—copper sulphate can be measured separately, then their algebraic difference should represent the temperature coefficient of the Daniell cell, except so far as it may depend upon the thermo-electric power of the liquid pair, zinc sulphate—copper sulphate, which is the only other contact of dissimilar substances in the cell.

So, also, if we combine the results obtained by measuring the thermo-electromotive force of zinc—zinc sulphate and mercury—mercurous sulphate in zinc sulphate, the result should be the temperature coefficient of a Clark standard cell.

§ 1. *To determine the Thermo-Electric Power of Zinc—Zinc Sulphate.*—For this determination it is necessary to have two contacts of zinc, and a solution of its sulphate so related that one can be kept at a constant temperature, while the other is brought to successive different temperatures. Two stout glass tubes, about 4in. (10cm) long and ¾in. in diameter, were connected near the tops by a narrow glass tube, 10in. (25cm.) long. This will be called the "experimental cell." It was filled with zinc sulphate solution saturated at zero, and two zinc wires about a foot in length were suspended so as to dip ½ or ¾in. into the liquid. The immersed ends were slightly amalgamated. Two thermometers were hung from a convenient support, so that their bulbs dipped into the solution at the same depth as the zinc wires. The liquid filling the small tube served to make the electrical connection between the two limbs.

The electromotive force was measured by the following method:—R and R′ in Fig. 1 are two resistance boxes of 10,000 ohms each. For most purposes R′ may be less than 10,000. They must be of the most exact adjustment, or the errors, if any, must be known. They are connected in series with a good Leclanché cell of higher E.M.F. than a standard Clark cell. Two Daniell cells would, perhaps, answer as well, but they are not so convenient.

The total resistance in the circuit must be kept at 10,000 ohms, partly in R, and the remainder in R′. In a derived circuit from A B, the terminals of R are placed in series a Clark cell S C, the experimental cell E C, and the long coil galvanometer G. It is better to include a resistance of 10,000 or 20,000 ohms besides in this circuit. The standard cell must be so connected that its positive is joined to the same terminal as the positive of the main circuit Leclanché cell L C. A key must be placed in both circuits, preferably a double successive contact key of the style used with a Wheatstone's bridge. The first points coming in contact close the main circuit; increased pressure brings the second pair of contact points together, closing the derived circuit. When the pressure is relieved, the derived circuit opens first, and finally the main circuit.

The adjustment consists in changing the resistance in the two boxes, keeping their sum 10,000, till the closing of the circuit does not cause the galvanometer needle to swing. A balance then subsists between the E.M.F. of S C and the fall of potential in the main circuit over the resistance between A and B. The cell E C is not included in the derived circuit in this first balance. The E.M.F. of the standard cell being known, the fall of potential over a single ohm in the main circuit is then known.

The galvanometer employed was a Thomson reflecting instrument, astatic, and having a resistance of 7,000 ohms. A change of a single ohm from R to R′, or the reverse, when the balance is nearly effected, is perfectly evident in the swing of the mirror. In fact, when a balance has been secured, if the key is kept closed for two or three seconds, the polarisation of the main circuit Leclanché cell is always evident in the overthrow of the balance.

The next step is to include the experimental cell in the circuit, as shown in the figure. Both limbs are surrounded with broken ice, and their temperature is nearly or quite the same. It is usually necessary to change the resistance R by a small number of units, perhaps two or three, in order to restore the balance.

One of the limbs is then heated by successive stages, using a bath of warm water. The temperature is allowed to become as nearly stationary as possible, and a balance is again brought about as before. If the resistance R must be increased to bring the galvanometer needle to zero, then the E.M.F. of the experimental cell is so directed as to place the cell in series with the standard cell. If R must be diminished to secure a balance, the experimental cell E C is in opposition to the standard. The closing of the key, therefore, indicates at a glance which pole of E C is positive. For if E C is in series with S C, the galvanometer needle will swing in one direction; if in opposition to S C, it will swing in the other direction; and the direction of the swing always indicates to the operator whether R must be increased or diminished to effect a balance.

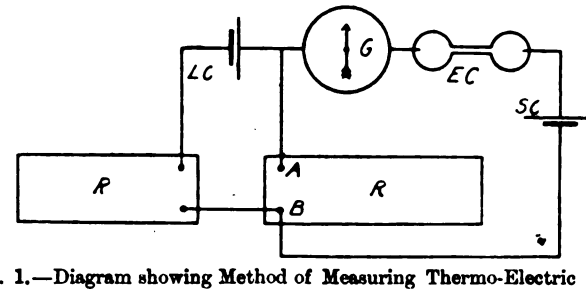

FIG. 1.—Diagram showing Method of Measuring Thermo-Electric Power.

With zinc in zinc sulphate the heating of one limb always produces an E.M.F. tending to make the zinc in the cold the positive plate, or to produce a current *from cold to hot through the cell.* The zinc in the cold limb acts like the zinc of a simple voltaic couple.

The table gives the data of one series of experiments,

Table I.

Temp. C. Left limb.	Temp. C. Right limb.	Temp. difference (corrected).	Resistance in R to balance.	Change in E.M.F. in legal volts.	E.M.F. per degree C.
0·6	0·4	0·2	9141	...	...
9·8	0·4	9·2	9183	0·00660	0·00072
14·4	0·4	13·8	9199	0·00911 ?	0·00065 ?
19·0	0·4	18·4	9225	0·01319	0·00072
27·8	0·4	27·2	9269	0·02011	0·00074
37·6	0·4	37·0	9320	0·02812	0·00076
47·3	0·4	46·7	9377	0·03707	0·00079

The observation marked doubtful I had reason to think included an error in making the balance.

The mean thermo-electric power for a temperature of 23°·85 C. is, therefore, 0·00079.

§ 2. *Thermo-Electric Power of Copper—Copper Sulphate.*—The apparatus was set up in precisely the same manner as before, with a solution of chemically pure copper sulphate of density 1·11. Two freshly electro-plated copper wires were used as electrodes to dip with the thermometers into the solution. The current produced on heating one limb was

* Extract, communicated by the author, from a forthcoming work on "Primary Batteries."

Digitized by Google

found to have the same direction as in the case of zinc sulphate, viz., from the cold limb to the warm through the liquid. The copper in the cold acts like the zinc of a simple voltaic cell. The table following contains all the data :—

Table II.

Temp. C Left limb.	Temp. C. Right limb.	Temp. Difference (corrected).	Resistance in R to balance.	Change in E.M.F. in legal volts.	E.M.F. per degree C.
0·6	0·4	0·2	9129	...	...
5·1	0·4	4·5	9145	0·00252	0·00056
9·6	0·4	9·0	9166	0·00582	0·00065
16·1	0·2	15·7	9189	0·00944	0·00060
21·7	0·6	20·9	9216	0·01369	0·00066
32·1	0·5	31·4	9260	0·02061	0·00066
38·4	0·5	37·7	9295	0·02611	0·00069
44·7	0·6	43·9	9330	0·03162	0·00072
49·4	0·6	48·6	9353	0·03524	0·00073

The mean thermo-electric power for the copper—copper sulphate couple is, therefore, 0·00073 for the mean temperature of 25°C. The results for both zinc and copper immersed in their sulphates are plotted in the curves of Fig. 2, in which curve A refers to zinc and zinc sulphate, and curve B to copper and copper sulphate. The total E.M.F.s in legal volts, due to heating one limb are plotted as ordinates, and the differences of temperature as abscissas. It will be noticed that both are slightly concave upward, indicating an increase of the thermo-electric power with rise of temperature.*

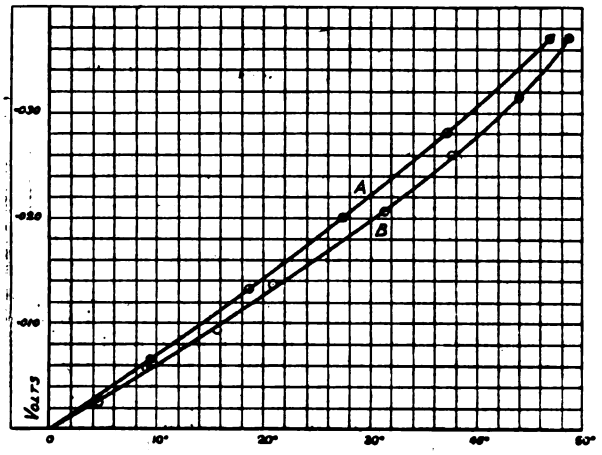

Fig. 2.—Thermo-electric power of $Zn - ZnSO_4$ and $Cu - CuSO_4$.

§ 3. *Application to a Daniell Cell.*—Since both zinc and copper, each in a solution of its sulphate, tend to become negative when heated, or to play the rôle of copper in a simple voltaic element, it is evident that they will exhibit the same phenomenon when set up together as a Daniell cell. When the entire cell is heated, the E.M.F. tends to rise because of the effect at the copper side of the couple, while the heating of the zinc and its sulphate gives to the zinc the power of generating a counter E.M.F. Whether or not the E.M.F. of the cell as a whole will rise or fall with rise of temperature depends upon the relative thermo-electric power at the two sides. The thermo-electric power of $Zn - ZnSO_4$ is a little greater than that of $Cu - CuSO_4$, so that the voltage of the cell falls by a very small coefficient per degree rise of temperature. The near equality of the two thermo-electric powers explains the small temperature coefficient of the Daniell cell.

* Since these experiments were made, the author has ascertained that similar ones were made by Bouty in 1880 (*Journal de Physique*, 1880, p. 229). Bouty made use of a similar method, but employed a Lippmann voltameter for electromotive forces. His results are 0·0006947 and 0·0006885 for zinc and copper in their own salts respectively, expressed as fractions of the E.M.F. of a Daniell. If it is assumed that the Daniell had an E.M.F. of 1·08 volts, the results of M. Bouty are 0·00075 for $Zn - ZnSO_4$, and 0·00074 for $Cu - CuSO_4$. Considering the small electromotive forces to be measured and the many disturbing causes, such as oxidation of the surfaces and convection-currents, the results are in very good agreement.

A little consideration will show that if the $Cu - CuSO_4$ side of a Daniell cell alone is heated, the E.M.F. of the cell will increase, while heating of the $Zn - ZnSO_4$ side alone will cause a somewhat greater decrease of E.M.F. The relative coefficients in the two cases were measured by setting up the experimental cell as a Daniell, making use of the same solutions that were used in the preceding determinations, and inserting in the small connecting tube between the two limbs a plug of purified asbestos to prevent intermixture of the two sulphates. After a balance had been obtained with a Rayleigh standard cell the experimental Daniell was substituted for it. A comparison of the E.M.F. of the two was thus made, and data secured to calculate the changes in the voltage of the Daniell by the subsequent heating. The resistance to balance the Rayleigh cell at 18·7°C. was 9134 ohms. The E.M.F. of the cell at this temperature is 1·434 legal volts. Hence the fall of potential over one ohm is 0·000157 legal volts. This constant is used to calculate changes in E.M.F. of the Daniell under test.

Table III.

Temp. C. $Zn - ZnSO_4$ limb.	Temp. C. $Cu - CuSO_4$ limb.	Corrected temp. difference.	Resistance in R to balance.	Change in E.M.F. in legal volts.	E.M.F. per degree C.
1·0	0·9	0·1	6935	...	...
10·8	0·8	9·9	6896	0·00612	0·00062
18·8	0·9	17·8	6864	0·01115	0·00063
29·6	1·2	28·3	6815	0·01884	0·00067

1·4	15·2	13·5	6994	0·00722	0·00053
1·4	26·4	24·7	7036	0·01382	0·00056
2·0	38·8	36·5	7087	0·02182	0·00060
1·4	40·0	38·3	7093	0·02277	0·00059
1·3	48·5	46·9	7129	0·02842	0·00061

The foregoing table of results justifies the anticipation respecting the changes in E.M.F.; for it will be observed that heating the zinc end of the experimental cell causes a marked diminution of the E.M.F., while the opposite result follows the heating of the copper end.

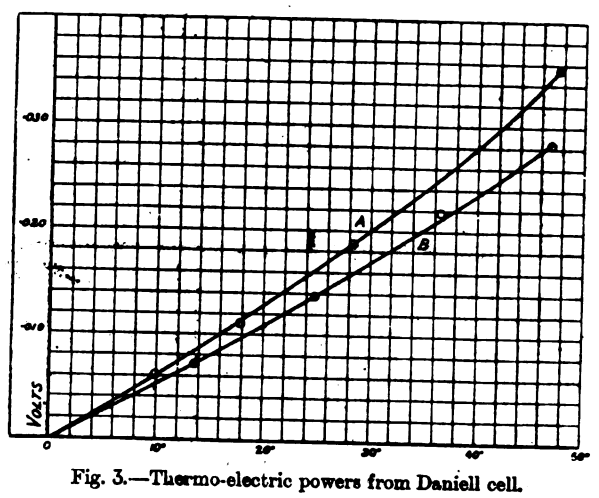

Fig. 3.—Thermo-electric powers from Daniell cell.

The coefficients in this case are both smaller than when each metal in its sulphate was used in both limbs of the cell. The difference is small in the case of zinc, but larger in the case of copper. Another series of measurements, made by heating the copper end of the chain, gave almost identical results.

The changes in E.M.F. resulting from heating one limb are positive, and from heating the other, negative. Both are plotted as positive ordinates in the figure, in order the better to compare them and exhibit the differences. Curve A (Fig. 3) belongs to zinc, and curve B to copper.

§ 4. *Temperature Coefficient of a Daniell Cell.*—A comparison of the thermo-electric powers of Tables I. and II. shows that the resultant effect upon a Daniell cell, due to heating

Digitized by Google

the cell as a whole, should be the difference of the two thermo-electric powers, or 0·00079 – 0·00073 = 0·00006 volt per degree, if the effect of heating the junction of the two sulphate solutions is negligible.

To investigate this last question, an experimental cell was made in which the connecting tube was curved so as to include a long U, and the junction of the two sulphates was at the bottom of this U when the cell was set up as a Daniell. After balancing in the usual manner, the U tube was placed in a hot-water bath, by which its temperature was raised from 17deg. to 52deg., or through a range of 35°C. No effect was produced upon the E.M.F. of the cell; or, if any, it was less than one ten-thousandth of a volt for the entire range of 35deg.

Many difficulties were encountered in the attempt to determine directly the temperature coefficient. They appear to be due to small changes in the E.M.F., occasioned by oxidation. The expedient was finally resorted to of setting up the experimental cell as a Daniell with amalgamated zinc and oxidised copper wires, and allowing the apparatus to stand for 15 hours. Consistent results were then obtained with both rising and falling temperatures. The whole cell, except the tops of the tubes, was immersed in water. The following data were obtained :—

Resistance to balance at 16°·8.....	6976	ohms
„ „ 57°·6.....	6956	„
„ „ 15°·2.....	6976	„

A rise of temperature of 48°·4 caused a diminution of 20 ohms to balance, while a fall of 42°·4 increased the requisite resistance 19 ohms. An independent balance with a standard cell gave the fall of potential over a single ohm as 0·0001561 volt. The mean value of the change in voltage per degree was accordingly 0·000073 of a legal volt. This is in very satisfactory agreement with the result calculated from the separate thermo-electric powers.

The E.M.F. of the experimental cell was 1·09 legal volts. Hence the temperature coefficient is 0·000073 ÷ 1·09 = 0·000067. The effect of a change of temperature on the Daniell cell is practically negligible. It is smaller than known disturbances which are assignable to other causes.

§ 5. *Thermo-Electric Power of Mercury—Mercurous Sulphate.*—Some chemically pure mercury was poured into each branch of the experimental cell, and on this was placed neutral mercurous sulphate, free from the mercuric form. Both branches and the thin connecting tube were then filled with a neutral solution of zinc sulphate saturated at 0°C. Connection was made with the mercury in each limb by sealing a long platinum wire into a glass tube, leaving a short portion of the wire exposed at the sealed end. This was pushed down into the mercury on either side.

The cell so set up was then immersed in melting snow and connected in series with the Rayleigh standard, as shown in the diagram, Fig. 1.

By the standard cell the fall of potential over each ohm in R was found to be 0·0001571 of a volt.

One limb of the experimental cell was then heated, while the other was kept at 0°C., with the results shown by the table.

Table IV.

Temp. C left limb.	Temp. C right limb.	Temp. difference.	Resistance in R to balance.	Total E.M.F. in legal volts.	E.M.F. per degree C.
0°	0°	0°	9150	...	...
8·30	0°	8·30	9161	0·00173	0·00021
14·50	0°	14·50	9170	0·00314	0·00022
20·70	0°	20·70	9179	0·00456	0·00022
26·70	0°	26·70	9288·5	0·00605	0·00023
35·80	0°	35·80	9204	0·00833	0·00023
42·60	0°	42·60	9219 ?	0·01053	0·00025 ?
49·25	0°	49·25	9226	0·01163	0·00024

The observation next to the last is marked doubtful because there was reason to suspect an error independently of the failure of this observation to agree graphically with the others.

In Fig. 4 the results are plotted in the curve B, together with those derived from zinc—zinc sulphate. These measurements include, of course, the effect of the contact of the platinum with the mercury, as well as that of $ZnSO_4$ and Hg_2SO_4. But these were purposely included with a view of analysing the temperature coefficient of the Clark cell.

The direction of the E.M.F. produced by heating the $Hg - Hg_2SO_4$ is such as to produce a current through the cell from the cold to the warm limb, precisely as in the preceding cases.

When, therefore, a Clark cell is warmed, there is a tendency to make both poles positive. The effect at the mercury or positive electrode is added to the whole E.M.F. of the cell, while that at the zinc or negative electrode is opposed to the E.M.F. of the cell, as a whole, and must be subtracted. The algebraic

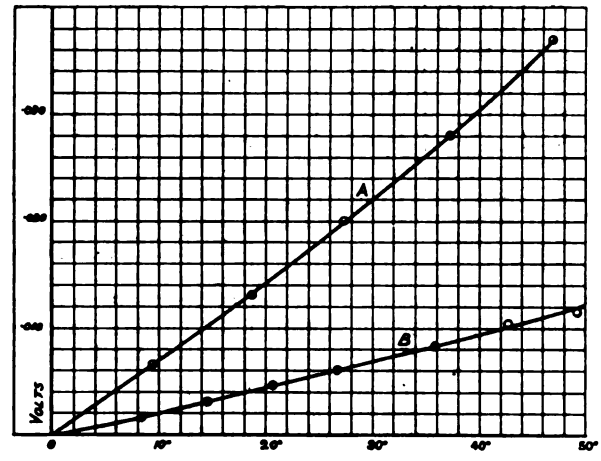

FIG. 4.—Thermo-Electric Power of $Hg - Hg_2SO_4$ and $Zn - ZnSO_4$.

result, then, is the difference of the two thermo-electric powers, and is negative because the $Zn - ZnSO_4$ one is numerically larger than the other. The difference is 0·00079 less 0·00024, or 0·00055.

These are the mean values of the thermo-electric powers. If we apply them to the corresponding equation for the E.M.F. of a Clark cell, involving only the first power of the temperature, we should write

$$E_t = E\,[1 - x\,(t - 15)\,],$$

in which x is to be found. In the writer's cells, with the solution used above, and with the zinc separated from the mercury salt, the E.M.F. is 1·44 true volts at 15°C.

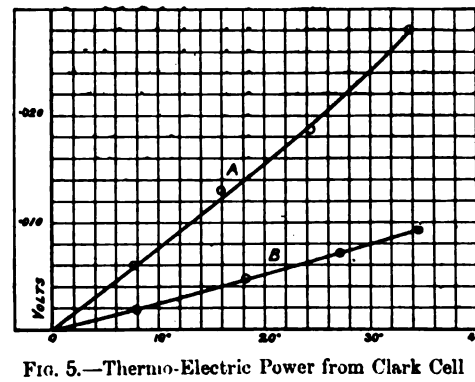

FIG. 5.—Thermo-Electric Power from Clark Cell

Hence $$E_t = 1{\cdot}44\,[1 - x\,(t - 15)\,].$$

If the difference between the thermo-electric powers at the two sides of the cell is the change in volts per degree, then from the preceding equations

$$Ex = 1{\cdot}44x = 0{\cdot}00055.$$

Whence $$x = 0{\cdot}000381.$$

Now, the thermal coefficient of such a cell by direct measurement is 0·000386 at 15°C. The agreement between the two methods is closer even than one might anticipate.

§ 6. *The Experimental Cell as a Clark Cell.*—By simply substituting an amalgamated zinc wire, dipping into the zinc sulphate, for the platinum wire of the last experiment, the experimental cell became a Clark standard. Heating up the

Digitized by Google

mercury side alone increased the E.M.F. of the cell; heating the zinc side alone reduced the E.M.F. The results are embodied in the table.

Table V.

Temp. C. $Zn + ZnSO_4$	Temp. C. $Hg + Hg_2SO_4$.	Temp. Difference.	Resistance in R to Balance.	Difference in E.M.F. in Legal Volts.	E.M.F. per Degree C.
15·75	15·8	0·05	9202	...	...
15·80	23·6	7·80	9214	0·00189	0·00024
16·00	34·2	18·20	9232	0·00472	0·00026
16·20	43·2	27·00	9247	0·00708	0·00026
16·25	50·7	34·45	9262	0·00944	0·00027
16·25	15·7	0·55	9207	...	...
23·25	15·7	7·55	9169	0·00598	0·00079
31·60	15·7	15·90	9124·5	0·01298	0·00082
40·00	15·7	24·30	9088	0·01872	0·00077
49·40	15·7	33·70	9029	0·02800	0·00083

The thermo-electric power is in both cases slightly higher than in the experiments on the same metals and their salts separately. But the difference of the mean values is 0·00056 as compared with 0·00055 of the last section. The temperature coefficient of the Clark cell, calculated as before, would be in this case 0·000388. It must be admitted that both of these results differ from the coefficient obtained by the ordinary direct method by a quantity well within the errors of observation.

The curve A of Fig. 5 shows the effect of heating the zinc end alone of the chain, and curve B the mercury end.

All of these curves are slightly concave upward, indicating a small increase of thermo-electric power as the mean temperature increases. Since the mean temperature in this last experiment was 33°, and in the preceding ones on the same metals and metallic salts separately was 24°, the higher values of the thermo-electric power obtained in the present case are partly due to the higher mean temperature.

THE SILVERTOWN PORTABLE TESTING SET.

This is a very compact collection of instruments for testing telegraph, telephone, and electric light circuits, contained in two small wooden boxes, of which one holds the batteries and the other the galvanometer, resistance coils, key, and commutators required for making the two most important measurements on such circuits. For connecting the battery to the testing instruments convenient leads are provided, terminated in brass plugs, with insulated handles for inserting in the proper plug holes. The instruments are connected up together in their own box in such a way as to secure the greatest economy of space, and to enable the two tests to be taken with the greatest readiness. The battery consists of two parts, viz., a set of Leclanché cells of low resistance, intended to be used in testing conductor resistances only; a set of 30 small Leclanché cells, having a total electromotive force of 45—50 volts, intended for measuring insulation resistances or other resistances of considerable magnitude, and subdivided into three sections of 10 cells each. The galvanometer consists of a coil of fine wire on a brass bobbin, in the centre of which a small magnetic needle with an aluminium pointer is hung in the same way as is usual in compasses. The pointer projects through the opening in the end of the coil, and the swing of the needle is limited by the size of the opening to about 45deg. on each side of the centre. The scale, which is a scale of equal currents, is approximately a scale of tangents, and is obtained empirically by calibrating the instrument. On the left-hand side of the box is placed the controlling magnet, which can be made to reduce the sensitiveness by about 40 per cent.

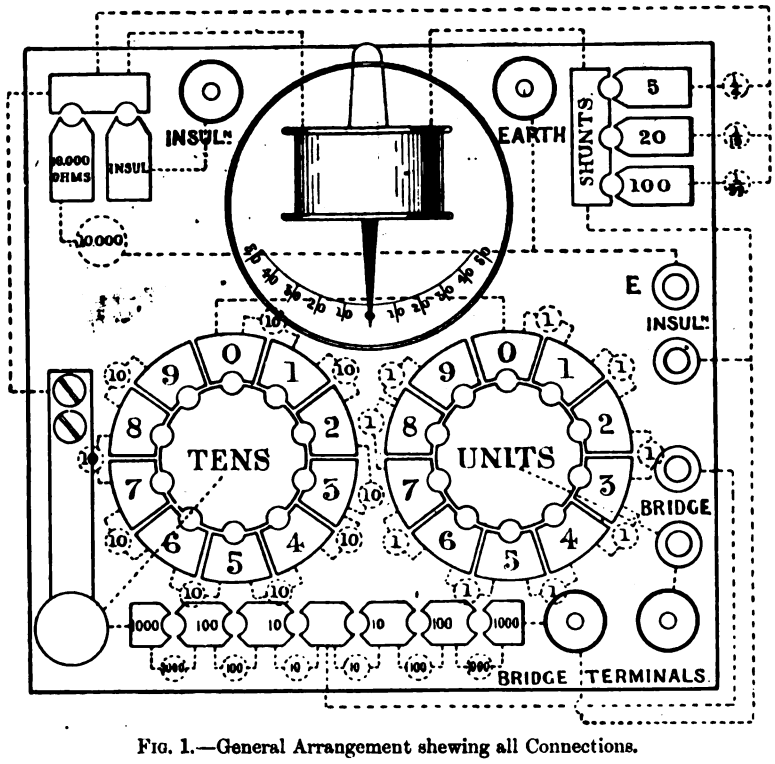

Fig. 1.—General Arrangement shewing all Connections.

Testing Conductor Resistance.—The method used of measuring the resistance of the conductor of the circuit under examination is that of Wheatstone's Bridge. The parts employed are the following:—The adjustable resistance, as will be seen (Fig. 1), consists of two sets of nine coils each connected to circular plug commutators or dials. One set of coils has nine resistances of 10 ohms each, making 90 ohms in all; the other has nine resistances of one ohm each, making nine ohms in all. The second part of the apparatus is the double set of proportional resistances, consisting of two coils of 10 ohms each, two of 100 ohms, and two of 1,000 ohms, these constituting the Bridge. The third part is the galvanometer, which has been already described. Its two terminals are connected to the two ends of the Bridge by depressing the contact key. The battery, as has been already described, consists of four Leclanché cells, having an electromotive force of about six volts.

Digitized by Google

The connections are made by inserting the plugs at the ends of the battery leads, in the two holes marked *Bridge*, and immediately this is done the current is established in the coils; the galvanometer circuit is, of course, not completed till the key is depressed. The ends of the conductor to be tested are to be secured under the two terminals marked *Bridge Terminals*, and in measuring low resistances care must be taken that they are very securely attached. Except in testing at the extreme range of the instrument, *i.e.*, quantities less than one ohm or greater than 1,000 ohms, the galvanometer will be found amply sensitive. The battery should be in circuit as short a time as possible, to avoid running down the cells, and it is well to take out one of the battery lead plugs when any alterations are being made in the plug commutators, only replacing it just before pressing the galvanometer key. Care should be taken to connect the conductor to be tested very securely to the bridge terminals. This may be done for very large or stranded conductors either by soldering to their ends thin brass plates with holes in them of a suitable size to go under the heads of the terminals, or the connection may be made by means of finer wires soldered to the ends of the main conductor. The resistance of these must be independently ascertained and subtracted from the gross result.

suppose that a given battery produces on the needle of a galvanometer placed in series with the insulation of a cable in the manner described a deflection of 10·3 divisions, and that on substituting a resistance of one megohm for the insulation we get 42 divisions, we find that the insulation resistance is $\frac{4 \cdot 2}{10 \cdot 3}$ megohms = 4·1 megohms approximately.

The diagram (Fig. 2) shows only those parts of the apparatus and their connections that are used in this measurement; those which relate only to the measurement of conductor resistances being omitted. The arrangement, it will be seen, is as follows: One pole of the battery is connected by a conductor ending in an ebonite-headed plug to the lower of the two plug holes marked *Insul*ⁿ. Thence the current passes along a connecting wire to a block marked *Shunts*, and thence through the galvanometer to the upper block on the other side. From the upper block on the left-hand side the current may take two paths, according as the hole marked *Insul*ⁿ or that marked *10,000 ohms* is plugged; if neither is plugged, the circuit is broken and no current can pass. This plug forms consequently a convenient make and break key. If the hole marked *Insul*ⁿ is plugged, the current passes to the terminal marked *Insul*ⁿ, so through the insulating covering of the cable to the outside sheathing or earth, back to the terminal marked *Earth* and the plug hole

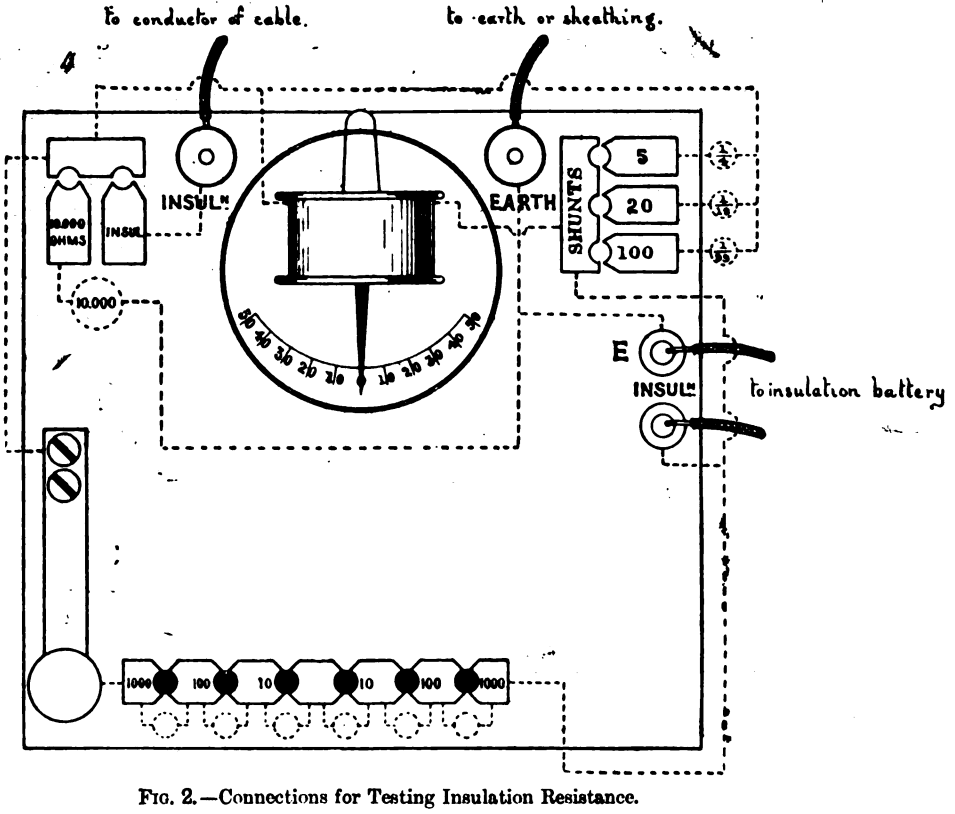

FIG. 2.—Connections for Testing Insulation Resistance.

Measurement of Insulation Resistance.—This is a measurement of the electrical resistance of the insulating material of a cable to the passage of a current from the inside conductor through the insulation to the lead sheathing, wet yarn, armour, or other outside conducting surface, and the inverse of the insulation resistance is the insulation conductivity, or, as it is generally termed, the leakage. This measurement is effected by the method of direct deflections. It consists in passing a current from a battery through a galvanometer into the conductor of a cable whose farther end is free and disconnected, thence through the insulating material to the outside coating or earth, and so back along a temporary conductor to the other end of the battery, the deflection of the galvanometer needle produced by this current being noted. Replacing that part of the circuit which was formed by the insulating material of the cable by a standard resistance of known value, we obtain a new deflection of the galvanometer needle. The quotient obtained by dividing the deflection produced by the current through the standard resistance by that through the cable insulation is a measure of the insulation in terms of the standard. Thus, for example, marked E, and then along the lead to the other pole of the battery. If, however, the hole marked *10,000 ohms* be plugged, the current will pass through a coil of 10,000 ohms, then along a connecting wire to the plughole E, and so back to the battery.

The test, then, consists in:—(1) Noting the deflection obtained when the 10,000 ohm hole is plugged; (2) in transferring the plug to the hole marked *Insul*ⁿ, and again noting. On dividing the deflection on the scale obtained when taking the constant by the deflection obtained in the second part of the test, and multiplying the deflections by the shunt or shunts employed, we obtain the insulation resistance of the cable in megohms.

Terrestrial Magnetism.—One result of the magnetic researches of M. Moureaux and others is to render practically obsolete the old-fashioned magnetic charts with their mathematically regular curves. M. Moureaux is engaged in drawing up charts showing the "isanomel" lines, or curves, passing through the points of maximum abnormality.

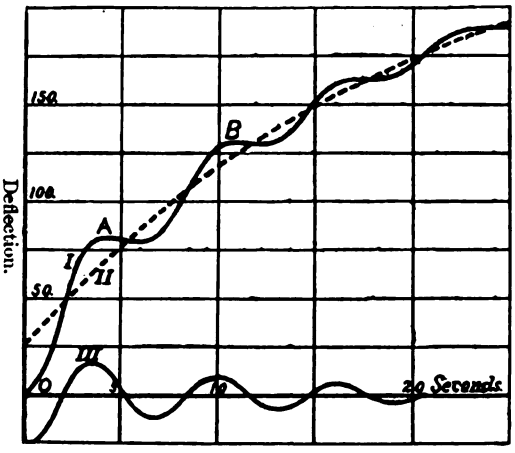
CERTAIN PECULIARITIES IN THE BEHAVIOUR OF A GALVANOMETER WHEN USED WITH THE THERMOPILE.*

BY ERNEST MERRITT, M.E.

When a galvanometer, whose needle is not too thoroughly damped, is used in connection with a thermopile, a curious phenomenon is observed. On suddenly exposing one face of the pile to some source of radiant heat, the needle of the galvanometer moves quickly to one side. In a short time, however, the motion becomes less rapid, and in the course of a few seconds the needle comes to rest, and in many cases moves backward for a short distance. This behaviour is then repeated, and it is only after a long series of such throws, which gradually become less and less marked, that the final steady deflection is reached. The curve O A B in the accompanying figure represents graphically this peculiar motion as observed in the case of a Thomson tripod galvanometer, the abscissa of any point on the curve showing the time that has elapsed since the beginning of the motion, and the corresponding ordinate being proportional to the deflection of the needle from its position of rest. With a galvanometer whose needle is more nearly "dead beat" the maxima and minima, which are so clearly shown in the figure, may not be present; but the general form of the curve will still be the same.

The effect described above was noticed in 1884 by Violle† while using a thermopile to investigate the radiation of molten platinum and silver. Numerous observations of successive maxima and minima are given in his Paper; but no explanation of the phenomenon is offered. Messrs. Rubens and Ritter have observed a similar phenomenon with a peculiar form of bolometer which they used for quantitative measurements of electro-magnetic waves;‡



Curve of the deflections of a Thomson tripod galvanometer in circuit with a thermopile suddenly exposed to source of radiant heat.

and numerous experiments that have been made in the laboratory of Cornell University, with a bolometer of the ordinary type, and with a number of different galvanometers and thermopiles, seem to show that this behaviour is not peculiar to any one instrument, but is always observed when a bolometer or thermopile, in circuit with a galvanometer, is *suddenly* exposed to radiant heat. The writer's attention was first called to the phenomenon in 1888, while engaged in an investigation of the energy of the light from incandescent lamps. In a Paper published during the following year attention was directed to the fact, which at that time rested only upon experimental grounds, that the first throw of the needle, under the circumstances described above, bears a constant ratio to the final deflection, this ratio being independent of the intensity of the radiation to which the pile is exposed.

The phenomenon appears to be due to the inertia of the galvanometer needle, and to the fact that a considerable time elapses after the pile has been exposed to a source of heat, before a constant temperature is reached. On account of its inertia the needle is unable to follow immediately the rapidly increasing current that flows when the face of the pile is first exposed. In a short time, however, the continued action of the deflecting force imparts sufficient velocity to carry it not merely to the position which corresponds to the current then flowing, but to a considerable distance beyond this point. The result is that the motion of the needle is stopped, and a retrograde movement begins, which continues until the pile has been heated sufficiently to cause another throw forward. This behaviour is then repeated until the temperature of the pile has become constant, or until the oscillatory motion of the needle has been destroyed by damping.

On the assumption that the heating of the pile takes place according to Newton's law of cooling, the difference of temperature T, at any instant t, of the two faces of the pile, is related to T_0, the final value of this temperature, by the equation

$$T = T_0 (1 - e^{-kt}) \quad . \quad . \quad . \quad . \quad . \quad . \quad (1),$$

where k is the radiation constant of the surface. The current generated by the pile, and hence the deflecting moment, acting on the needle of the galvanometer, is proportional to T. The writer considers the mathematical theory of the motion of the needle of a damped ballistic galvanometer under the action of such a deflecting couple, and shows that the deflection θ at any moment must be such as to fulfil the equation

$$\theta = T_0 \left[C e^{-kt} \cos \left(\frac{2\pi t}{\tau} + \phi \right) - m e^{-kt} + l \right] \quad . \quad (2)$$

where the constants of the different terms within the bracket are all independent of T_0, the final difference of temperature of the pile.

The motion represented by this equation evidently possesses all the characteristics of that shown in the figure. It may be looked upon as resulting from the combination of two motions, one of them being a steady increase of deflection in accordance with the logarithmic curve represented by the last two terms of the equation, the other a motion of oscillation with gradually diminishing amplitude, as indicated by the first term.

To test the above equation, a series of observations was made with a Thomson tripod galvanometer, every precaution being taken to secure a constant source of heat, and to avoid errors due to draughts of air, magnetic disturbances, &c. The period of vibration of the needle, and its logarithmic decrement (with the thermopile in circuit) were first determined by the ordinary methods. Data for the curve shown in the figure were then obtained by recording on a chronograph the times of the successive maxima and minima, and the time at which the needle passed each tenth division of the scale. Assuming that the equation derived above truly represented the motion, the curve was then analysed into its two components, and after a few trials curves II. and III. of the figure were obtained. These two, when combined, give exactly the motion that was observed, while both are capable of being quite accurately represented by equations of the form indicated in (2). For example, curve II. was found to agree closely with the equation:

$$\theta' = 310 - 283\, \epsilon^{-0.037t},$$

the differences between observed and computed values of θ' in no case exceeding 2 per cent. The time of vibration of the needle, as computed from curve III., was found to be 6·1 seconds, while that observed when the needle was allowed to swing freely was 6·0 seconds. The observed and computed values of the ratio of damping show a similar close agreement, being equal to 1·28 and 1·31 respectively.

The fact, which has already been mentioned, that the first throw of the needle bears a constant ratio to the final deflection, is confirmed by equation (2). Since T_0 is a factor of the right hand member of the equation, and since the expression inside the bracket is independent of T_0, the only effect of a change in the intensity of the source of heat would be to increase or diminish all the ordinates of curve I in the same proportion, the ratio of any two ordinates remaining the same. If, therefore, the final deflection of the needle is proportional to the quantity of heat received by the pile, the first throw will also be proportional to this quantity, and may in all cases be used instead of the final deflection. Experiments made in 1888 to test the above conclusion showed the ratio to be constant for deflections ranging from 100mm to 20mm. The observations have been since repeated, using great care to avoid as far as possible all sources of error, and the following results were obtained as the mean of a number of measurements:—

First throw.	Final deflection.	Ratio.
53·0 mm.	196·0 mm.	0·270
36·5 „	136·7 „	0·265
17·75 „	65·0 „	0·273
5·25 „	19·75 „	0·265

The slight irregular variations which occur might easily be accounted for by the unavoidable errors of observation, especially as the source of heat, an Argand burner, could not be relied upon as perfectly constant. The conclusion that the ratio is independent of the deflection seems, therefore, to be justified, at least in the case of the galvanometer used in these experiments.

The importance of this conclusion will readily be seen by those who have had occasion to use a thermopile for accurate measurements of radiant heat. Draughts of air, and other almost unavoidable sources of temperature variation, frequently make the galvanometer quite unsteady, while the extreme delicacy of the instru-

Digitized by Google

ments that must be used in work of this kind renders them especially susceptible to magnetic disturbances. Many observations are thus made valueless by a change in the zero point of the galvanometer during the three or four minutes required for the needle to come to rest. Only a few seconds are required, however, for the first throw of the needle, and the change in zero point during this time would scarcely ever be sufficient to cause an appreciable error. The use of the first throw in place of the final deflection may therefore lead to greater accuracy as well as to a saving of time.

It will be observed that the principle underlying this method of taking readings is not confined to the case of the thermopile, but is capable of quite wide application, and is of especial advantage when the saving of time is a consideration. A number of experiments which are usually considered unavailable for lecture demonstrations have been quickly and accurately performed in this way under conditions that would render the use of the ordinary method entirely out of the question.

ELECTRIC LIGHTING AT GLASGOW.

At the ordinary monthly meeting of the Glasgow Town Council, on Thursday last week, the minutes of the Gas Committee contained a long report by the special sub-committee on electric lighting. The sub-committee recommended as follows :—

(1). That the Town Council should in the meantime, instead of transferring their powers to any outside person or company, themselves undertake the laying down of the necessary work and plant for generating and supplying electricity for private and public lighting within the compulsory or central area of the city, under such professional advice and superintendence as may be deemed requisite or expedient. (2). That the system of supply, mode of distribution, and other details connected with the proposed installation should, as far as may be found expedient, be in accordance with the reports obtained from Mr. Crompton, Professor Jamieson, and Sir William Thomson. (3). That, if the recommendations now made are approved, the matter be remitted back to the Gas Committee to arrange for acquiring a suitable site for the erection of a central supply station, and to take all other necessary steps for carrying out the proposed works. As will be seen from the report by Mr. Crompton, the cost of putting down the plant requisite for supplying 11,000 16 c.p. lamps (exclusive of cost of sites for central station and sub-station) is estimated at £51,307.

Mr. URE, in moving the adoption of the minutes, explained the recommendations of the committee at length. With regard to the first recommendation, he said a deputation had visited Bradford, and found that there seemed to be in the minds of those whom they met no serious difficulty in the way of a town council carrying on an undertaking such as this. As to the financial results, in the first few months in Bradford they showed a loss of £2,127. In that sum, however, was included £1,086 paid as a sinking fund. The capital expended was about £31,000. During the last six months the loss amounted to £315, and it was expected that in the course of a year the undertaking would be carried on at a profit. The Bradford people commenced selling electricity at fivepence per unit, but they had to raise the price to sixpence. With regard to the second recommendation, Mr. Ure explained that, although the committee had consulted Mr. Crompton, they were not bound to take his system or engage him. If the Council approved of the two first recommendations of the committee they would doubtless adopt the other, and remit to the committee to carry out their recommendations.

Mr. M'LAREN seconded the motion. In company with Mr. Ure, he had had the opportunity, on Monday last, of witnessing the inauguration of the latest installation in London. This installation confirmed his belief as to the wisdom of the recommendation of the committee with regard to the low tension system. All the appliances were the same as those now recommended.

Mr. J. U. PRIMROSE said he had studied all the reports of the committee, and all materials put before the Council. He had read the reports of the various experts, and he was confirmed in the belief that they were only justified in adopting the first of the three recommendations of the Gas Committee. He moved as an amendment that only the first recommendation be accepted. He felt that the Council had not yet emerged from the state of mere experiment, and they had no information put into their hands by experts sufficiently assuring to justify the Corporation in accepting the whole programme recommended to them by the Gas Committee.

Bailie PATON said Mr. Primrose must bear in mind that the sub-committee had spent a large share of time, and a great amount of effort, in getting the information which was now presented to the Council. The conclusion they had come to was one from which in general they would not be easily moved—that was to say, that the three wire low tension system was that which should be adopted in the compulsory area the Council were now asked to deal with. They knew quite well that at present the Council did not want to be committed, nor did the sub-committee wish to be specially committed, to any particular principle of carrying out the work. As to Messrs. Mavor and Coulsen, the sub-committee were not wishful to confiscate any man's property. They were anxious to deal fairly and honourably with Messrs. Mavor and Coulsen.

Mr. PRIMROSE said that, in view of the statement made by Bailie Paton with regard to the spirit dominating the committee, he would withdraw his amendment.

Mr. COLQUHOUN said he was sorry that Mr. Primrose had withdrawn the amendment, which he was just on the point of rising to second. If necessary, he was prepared to move the amendment which Mr. Primrose had abandoned, because he held they were not in a position to go further than affirm the general principle that the Town Council should keep the electric lighting in its own hands. But when the sub-committee asked the Town Council to commit itself to this low-tension system alone, he thought they were taking a course which, with their present information, would not be advisable. What was the position of the Council in this matter? They were bound to provide electric light for the whole city—not merely for the compulsory area. Within the compulsory area they were bound to provide electric light within a period of two years. But the electric lighting order went beyond that, and said that any six ratepayers in any portion of the City could come to the Corporation and demand a supply of electric light. Now, if they were under obligation to supply electric light to, say, six ratepayers in any outlying part of the city, what became of the suggestion that they should have a nice little compact area in the centre, which was to be worked on the low-tension principle? Because what they would undoubtedly have to face in the near future was that they would have a demand from outlying ratepayers. They had received a report from Mr. Crompton, who they knew was a great authority on the low-tension principle. With that report he would find no fault if they were dealing with the compulsory area alone; but that was not the position. Professor Jamieson did not in express terms in any part of his report say that if the whole city of Glasgow were to call upon them to supply electricity the low-tension system was the best. His report was a balancing of the conveniences and inconveniences of the rival systems. He avoided committing himself to what was best for the city as a whole. Sir William Thomson gave as his opinion that for the compulsory district alone the low-tension system was the best. But he had received a statement from Messrs. Mavor and Coulsen, in which he was a little surprised to find certain statements in a report by Sir William Thomson. In this report he found a series of questions put to Sir William Thomson and Sir William's answers. The first question put was this—"Is the system of high-tension distribution, hitherto adopted in Glasgow by this Company, the best for meeting the demand from isolated consumers scattered over a large area?" That was putting in a precise form the question which he (Mr. Colquhoun) would desire to put to Sir William Thomson, and his reply was as follows :—"The system of high-tension distribution hitherto adopted in Glasgow by your Company is the best for meeting the demand from isolated consumers scattered over a large area. No other system hitherto either practised or proposed is adapted to supply this kind of demand." He confessed that he was a little surprised when he found that Mr. Ure, in face of this document, gravely asked the Council to commit themselves to the principle of low-tension alone. He therefore moved that the minute be sent back to the sub-committee for further investigation, and that they should confine themselves to confirming the principle that they should keep the electric light exclusively in their own hands.

Mr. RICHMOND said that the committee who had charge of this matter had done their work well. They had had an enormous amount of labour, and they had given the Council a very good report. At the same time he had some doubt as to whether the recommendation was a safe one. Why should the Council tie their hands now with regard to the outlying districts by adopting this particular system, thereby making it prohibitory for those districts to get a supply?

Mr. URE said that there was no wish to prevent the extension of electric lighting. What they had to deal with just now was exclusively the statutory area.

The Council then divided, when 30 voted for the motion and 7 for the amendment.

LEGAL INTELLIGENCE.

In re the New Telephone Company.

An order has been directed by Mr. Justice North to be made in the matter of this Company, staying winding-up proceedings conditionally on an arrangement by which the debts would be satisfied being carried out.

Mr. Napier Higgins, Q.C., and Mr. Roger Wallace appeared.

TRADE NOTES AND NOTICES.

[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.]

"THE ELECTRICIAN"

ELECTRICAL TRADES' DIRECTORY & HANDBOOK for 1891.

The 1891 edition of our well-known Directory and Handbook is ready, price 5s., postage extra. The book consists of over 900 pages, and has entailed this year a heavy amount of work. The HANDBOOK DIVISION contains a mass of most useful information. The DIRECTORY DIVISION consists of 430 pages, and contains a very carefully compiled Alphabetical and Classified List of Firms and Persons engaged in the Electrical and Allied Trades in all parts of the world. This Division has been corrected up to date, and the book is thoroughly reliable, the very numerous changes which take place at the beginning of the year being incorporated. By the aid of this Directory, makers of Electrical Machinery, Apparatus, Instruments, Fittings, Sundries, Novelties, and other goods, may safely communicate direct with probable customers without the annoyance and great expense consequent upon using books which are mere lists of Members of Scientific Societies repeated again and again. The Colonial and Foreign Division of this Directory will be found extensive and reliable. *Orders should be forwarded at once.*

On Friday next "The Electrician" Company will publish "THE ELECTRICIAN" PRIMERS in two volumes, price per volume 2s. paper covers, 2s. 6d. cloth.

TENDERS INVITED.—The Caledonian Railway Company invite tenders for the supply of various stores, including crucibles, india-rubber, and telegraph instruments, for 12 months from August 1st next. Specifications may be obtained from Mr. James Lorimer, superintendent of stores, Caledonian Railway, Charles-street, St. Rollox, Glasgow; and tenders must be lodged with the secretary, Mr. John Blackburn, 302, Buchanan-street, Glasgow, not later than Monday, the 22nd inst. Further particulars will be found in our advertisement columns.

——— The Highland Railway Company invite tenders for the supply of various stores, including telegraph instruments and fittings and telegraph construction material, for 12 months from July 1st next. Forms of tender may be obtained from Mr. J. G. Bulmer, storekeeper, Inverness; and tenders must be lodged with Mr. A. Dougall, secretary, Inverness, by the 20th inst.

——— The Lisburn (Ireland) Town Commissioners invite tenders for lighting the town either by electricity or gas. Specification can be seen at the office of the town clerk, Mr. R. Young, Railway-street, Lisburn, and tenders must reach him not later than 12 noon on Saturday (to-morrow).

FOR SALE.—Messrs. Wheatley Kirk, Price, and Goulty announce that they have for disposal the business carried on as Quentin Matsy's Forge, 14, Griffin-street, York-road, Lambeth, London, S.E., together with the machine tools (by Whitworth, Muir, and others), engine and boiler, loose appliances, stock of fancy wrought iron electroliers, &c. Further particulars will be found in our advertisement columns.

MESSRS. BEREND AND CO.—This firm are making some considerable alterations in their establishment, and shortly intend opening a showroom for the display of the various electrical instruments, bronze ware, &c., for which they are agents in this country.

MR. E. S. HINDLEY.—We have received a copy of Mr. Hindley's list, No. 234, which contains illustrated particulars and prices of a number of his well-known manufactures, including horizontal and vertical engines and boilers, donkey feed pumps, fly-wheel steam pumps, circular saw benches, &c. The list can be kept in the pocket, and contains a quantity of useful information.

MESSRS. W. H. WILLCOX AND CO.—This firm announce that they will have on view at the Royal Agricultural Show, to be held at Doncaster, on June 20th, 22nd, 23rd, 24th, 25th, and 26th next, a large selection of engineers' stores, oils, tools, &c.

BATTERY ZINCS.—Messrs. David Moseley and Sons send us a specimen of their new battery zincs, which are composed of a number of sheets of thin zinc, separately amalgamated, and arranged as concentric tubes or as bundles of flat plates. The advantages claimed are that the thin zinc is purer than the ordinary sheets, that the amalgamation penetrates the whole thickness, and that it is found that no cleaning or scraping is necessary. We understand that these zincs have been well tried by some of the telephone companies.

BOOKS, &c., RECEIVED.

"Siemens und Halske auf der Internationalen Elektrotechnischen Ausstellung zu Frankfurt-a.-M., 1891."

"The New General and Mining Telegraph Code." By G. Algernon Moreing, M.I.C.E., and Thomas Neal. (London: William Clowes and Son.)

"The Arithmetic of Electrical Measurements." By W. R. P. Hobbs. (Revised Edition.) (London: Thomas Murby.)

COMPANIES' MEETINGS & REPORTS.

The Anglo-Portuguese Telephone Company (Limited).

The adjourned fourth ordinary general meeting of this Company was held at the offices of the Company, 53, New Broad-street, E.C., yesterday, for the purpose of receiving Directors' report and accounts for 1890, to elect two directors and auditors, and to transact the general business of the Company. Sir Alexander Armstrong, K.C.B., F.R.S., presided.

Mr. R. Rodgers (the Secretary) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN: Gentlemen, in rising to move the adoption of this report, I can do so with very great satisfaction. As you will see, there has been a steady increase of business throughout. The amount to the credit of profit and loss account, after making all reductions, and including the balance brought forward from last year, is £6,193. 15s. 6d. Out of this an interim dividend of 5 per cent. has since been paid, absorbing £2,500, and of the balance it is now proposed to place £2,500 to reserve, and to carry forward £1,193. 15s 6d. to the current year's accounts. I should like to mention, in regard to the reserve fund, that this time last year it stood at £6,000, while it now amounts, with the addition we are making, to the respectable figure of £8,500. The number of paying subscribers up to December 31st has been very satisfactory. At Lisbon there were 1,024, and the gross annual value of them was £7,530. At Oporto the number was 983, of a gross annual value of £5,391, making a total of £12,921, showing an increase in subscribers of 152, and in annual gross value of £1,033 over the preceding year. Now, that was at December 31st, but the account has been since further extended, and I may mention for your information that up to May 31st the total number of the figures is as follows:—At Lisbon 1,085 subscribers, paying an annual income of £7,950, and at Oporto 1,009 subscribers, paying £5,636. The net gross income of the Company up to May 31st is no less than £13,586. It was at the 31st December only £12,921, and it now stands, as I have stated, at £13,586. The increase since December has been 61 subscribers for Lisbon and 26 for Oporto, which had given us in cash £665 up to date—that is, for five months. The average rate of increase is considerably higher than last year, and if it goes on increasing at the same rate to the end of the year, the increase in the number of subscribers will be 210, and an annual income of £1,660. I can hardly fancy, considering the disturbed state of affairs recently in Portugal, and the crisis through which it has passed, that the shareholders will regard the balance as shown in these accounts as other than satisfactory touching the working of the telephone, and I look forward to a very great success now that we have got through the crisis satisfactorily. There has been a little diminution in the payments, but this is cumulative, and they will come out all right in the end, and I think that we may fairly congratulate ourselves and the shareholders upon the satisfactory state of things considering the very disturbed state of Portugal and the bad feeling which existed touching English enterprise. It does not occur to me, gentlemen, that I have anything more to say, and I will simply content myself with moving the adoption of the accounts. I may, however, say that the Directors have the pleasure to announce that Conde De Gouveia and Mr. Pinto Basto have rejoined the Lisbon Board, and that Dr. Marcal Pacheco had been re-appointed the Company's legal adviser in Portugal. So far all matters between the Board in Lisbon and the Board here are in efficient working order. I do not know, gentlemen, that I need do any more than move that the Directors' report and accounts for the year ended December 31, 1890, be received and adopted.

Mr. C. L. W. FITZGERALD seconded the motion.

No questions were asked, and the resolution was at once put and carried.

The CHAIRMAN: I have now to move that Mr. C. L. W. Fitzgerald be, and he is, hereby re-elected a Director of the Company.

Mr. R. VAN ZELLER seconded the motion, which was carried.

The CHAIRMAN then proposed that the Conde De Gouveia should be re-elected a member of the Lisbon Board.

Mr. FITZGERALD seconded the motion, which was carried.

The retiring auditors, Messrs, Deloitte, Dever, Griffiths and Co., were re-elected.

A vote of thanks having been accorded to the Chairman and Directors,

The CHAIRMAN, in reply, expressed the hope that upon the next occasion he would have a very satisfactory account to lay before the shareholders.

The meeting then separated.

China and Japan Telephone Company (Limited).

The eighth ordinary general meeting of the shareholders of the China and Japan Telephone Company (Limited) was held at the registered office of the Company, 14, Austin Friars, on Tuesday last, for the disposal of the following business: To receive the Directors' report and the audited accounts; to elect a Director in place of the one retiring, but who is eligible for re-election; to appoint auditors for the ensuing year and fix their remuneration; and such other business as might be brought before the meeting. Mr. H. Grewing presided.

Mr. ALEX. B. CHALMERS (the secretary) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN: Gentlemen, I have a few remarks to make in addition to those contained in the report, which we are now asking you to adopt, together with the accounts. The general result when compared with the previous year is rather better. Both revenue and profits on sales have increased, but the net result is only slightly more favourable. The reason is that it had become absolutely necessary for sanitary reasons to remove our exchange at Shanghai from the old quarters to healthier premises, and this has entailed a considerable outlay of close upon £140, which, of course, will not occur again, we hope, for many years, and which has had to come out of the net profit. The long expected opening up of China generally to Western enterprise is still a matter for the future, and we continue to be limited to only two cities in China, which, in point of fact, are the only two cities where it pays to have the telephone introduced, they being the only places which are sufficiently inhabited by European merchants and such as use the telephone. The exchanges at Shanghai and Hong Kong themselves, though very limited in their operations (they are not very large places), are receiving every possible attention both from ourselves and from our managers, and may be said to be capable of some further development. Now, with regard to the balance of net profit shown in the accounts, we have considered it right to recommend that this should be carried forward. There is, in the first place, the question of our debentures to be considered. They are held by the Oriental Telephone Company, and it is true that when, at the end of last year, they became due, they were renewed by that Company, but still only for a further period of five years, and they will become due again at the end of 1895, and we think it prudent, therefore, that some provision should gradually be made in respect to them; and besides that, we have to bear in mind that we may require a further sum, however moderate, in connection with future extensions, and also in order to develop in every way we possibly can the sales business. As there is no capital—no working capital—available, we are of necessity compelled to fall back on the revenue—or upon such part of the revenue as remains available after the expenses are paid. During the year, or rather toward the end of last year, I am sorry to say we lost, by death, our late Chairman, Mr. H.G. Erichsen His loss has been very sincerely regretted by us, as his assistance and advice ever since the formation of the Company has been of the greatest service to us. I think, gentlemen, these are all the observations that I have to make, and I beg to move—

"*That the Directors' report and the audited accounts for the period ended December 31, 1890, be, and the same are hereby, approved and adopted.*"

Mr. LLOYD seconded the motion.

No questions were asked.

The motion was then put, and carried unanimously.

It was then moved by the CHAIRMAN, and seconded by Mr. ADDISON:—

"*That Thomas Lloyd, Esq., be, and he is hereby, re-elected a Director of the Company.*"

The motion was carried.

Mr. LLOYD briefly returned thanks for his re-election.

Mr. H. A. HENTSCH moved, and Mr. J. M. M'LEOD seconded:—

"*That Messrs. Price, Waterhouse, and Co. be, and they are hereby, re-elected Auditors of the Company for the year 1891, and that their remuneration for that period be the sum of 10 guineas.*"

The motion was carried.

Mr. ADDISON moved: –

"*That the sum of 200 guineas be voted to the Directors as remuneration for their services during the past year, such sum to be divided as they may elect.*"

Mr. HENTSCH seconded, and the motion was carried.

The CHAIRMAN, in acknowledging on behalf of himself and colleagues the vote of 200 guineas, said that the interests of the Company would always be in the future, as they had been in the past, their first consideration. There was no further business before the meeting, and he had only to thank the shareholders for their attendance.

A vote of thanks to the Chairman and Directors for their services having been made, the meeting then separated.

Electric and General Investment Company (Limited).

The following is the report of the Directors for the period ending May 31st last, to be presented to the shareholders at the second ordinary general meeting of the Company, at Winchester House, Old Broad-street, on Wednesday, the 17th inst., at three o'clock:—

The Directors beg to submit with this report a statement of the accounts for the period ended May 31, 1891, showing a net profit of £2,592. 6s. 0d. available for distribution, which the Directors recommend should be appropriated as follows:—That a dividend of 10 per cent., together with a bonus of 12s. 6d. per cent., be paid on the capital paid-up on the ordinary shares, that £269. 10s. 9d. be placed to reserve, that a dividend of £1. 5s. 0d. be paid on each founders' share, that £59. 4s. 6d. additional remuneration be paid to the Directors, in accordance with Articles of Association, and that £16. 10s. 9d. be carried forward in equal moieties on account of the ordinary and founders' shares.

A large number of proposals of various kinds have been submitted to the Board, all of which have received careful consideration, and such as seemed suitable for this Company to take up have been fully investigated, but, in view of the great financial depression which has existed for some time past, the Directors have had to proceed with great caution. The Board have now certain important matters in hand, which they have every reason to hope will be successfully dealt with and prove remunerative.

The auditors, Messrs. Rait and Kearton, offer themselves for re-election.

NEW COMPANIES REGISTERED.

ALBERT ELECTRIC LIGHTING COMPANY (LIMITED).—Registered by Bonner, Wright, Thompson, and Co., 165, Fenchurch-street, E.C., with a capital of £10,000, in £5 shares. Object: to carry on the business of electricians, mechanical engineers, &c.

AURORA ELECTRIC LIGHTING AND DISTRIBUTION COMPANY (LIMITED).—Registered by F. Ridley, 52, Leadenhall-street, E.C., with a capital of £25,000, in £1 shares. Object: to establish, carry on, and develop, in the United Kingdom and abroad, the business of an electric light and power company in all its branches.

BIBBY STEAMSHIP COMPANY (LIMITED).—Registered with a capital of £300,000 in £1,000 shares. Objects: to carry on the business of ship owners, ship brokers, insurance brokers, engineers, electricians, &c.

BOURNEMOUTH AND DISTRICT ELECTRIC SUPPLY COMPANY (LIMITED).—Registered by Renshaws, 2, Suffolk-lane, E.C., with a capital of £50,000 in £5 shares. Object: to acquire the right of supplying electricity for light or power, heretofore carried on at Bournemouth by the Brush Electrical Engineering Company (Limited), in accordance with an agreement expressed to be made between the Brush Electrical Company of the one part and the Company of the other part, and to carry on the business of electrical engineering in all its branches. There shall not be less than three nor more than seven Directors. The first are John Fair, William Fisher, D. M. Fox, J. Atkinson Hosker, G. J. Piercy, A. H. Sanderson, and L. Scarth. Qualification, 20 shares. Remuneration to be determined in general meeting.

COMMERCIAL CONTRACT CORPORATION (LIMITED).—Registered with a capital of £50,000 in £1 shares. Among the objects are the manufacturing and dealing in any machinery or apparatus for the production and supply of steam, water, electric, or other motive power.

CITY NOTES, &c.

AMERICAN BELL TELEPHONE COMPANY.—A quarterly dividend has been declared of 3 per cent., with 6 per cent. extra.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the past week amounted to £5,798.

BRITISH INSULATED WIRE COMPANY (LIMITED).—A private meeting of shareholders of this Company was held at the Cannon-street Hotel on Wednesday.

CITY AND SOUTH LONDON RAILWAY COMPANY.—The traffic receipts of this Company for the past week amounted to £776. The aggregate receipts for the half-year to date are £16,919.

COMMERCIAL CABLE COMPANY.—This Company announces a quarterly dividend of 1¾ per cent. upon the outstanding stock, payable July 1st. The transfer books will be closed from June 20th to July 2nd.

NATIONAL TELEPHONE COMPANY (LIMITED).—Application has been made to allow the further issue of 8,250 shares and £70,000 Four and a-Half per Cent. Debenture Stock, to be quoted in the Official List.

NOTTING HILL ELECTRIC LIGHTING COMPANY (LIMITED).—The Stock Exchange Committee have ordered shares Nos. 142 to 6,459 to be quoted in the Official List.

TRUSTEES, EXECUTORS, AND SECURITIES INSURANCE CORPORATION (LIMITED).—Sir John Pender and Mr. J. Denison Pender have ceased to be members of the Board of this Corporation.

THE ELECTRIC CONSTRUCTION CORPORATION (LIMITED).—A circular has been issued by this Company inviting the shareholders to take up the balance of the issue of Debentures recently made.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended June 5, 1891, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,546.

CRICKET.—A cricket club has been formed by the *employés* of Messrs. Laing, Wharton, and Down, 82A, New Bond-street, W., and challenges are invited from any clubs in the electrical trades. Mr. J. H. Mackail is hon. sec. and treasurer.

THE NON-CONDUCTOR OF ELECTRICITY.

VULCANISED FIBRE,

PATENTED.

WAREHOUSE.

This new material is supplied in two qualities, Flexible and Hard.

The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 2ft. 6in., varying in thickness from 1-50in. to 1in.

FACTORY.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.

MOSSES & MITCHELL, 70, Chiswell-st., London, E.C.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 683.—Vol. XXVII. FRIDAY, JUNE 19, 1891. Price Fourpence.

NOTES.

The *conversazioni* of the Society of Arts at South Kensington and of the Royal Society at Burlington House being both held on Wednesday evening last, the overcrowding, which is the one drawback to such gatherings, was considerably reduced. The exhibits at Burlington House were of a very interesting and varied character. The electrical novelty of the evening, Prof. Perry's meter, is fully described in another column, but Prof. J. J. Thomson's induced discharges in vacua were carried out with such complete success, compared to the efforts which were made at a recent meeting at Cambridge, that they, perhaps, constituted the chief feature of interest to students of physical science. The residual glow in a bulb containing rarefied oxygen, persisting for more than half a second, appeared to be a thick yellow fog, and seemed to have an actual opacity. We understand that the spectrum is continuous, while with air the usual bright lines are seen. In hydrogen, no residual glow is found, nor has it been observed with CO_2. In some of the experiments, primary coils of glass tube filled with mercury were used, and in others gutta-percha covered wires were employed. Mr. Wimshurst showed an influence machine working as a motor, and developing a good deal more power than might have been expected.

The beautiful and suggestive experiments on "electrical evaporation," exhibited by Prof. Crookes, have one great advantage over the electro-magnetic theory: they do not require a peculiarly receptive spirit to bring home conviction. On first reading Prof. Crookes' recent Paper, describing these experiments, we thought that he had preferred an apt title to an accurate one; but careful perusal showed us that if the phenomenon described is not of the nature of evaporation, it is difficult to see what it can be. One of the most interesting results of these investigations was the extraordinary power of occlusion exhibited by the freshly-evaporated platinum. Although the tubes were exhausted until very high vacua were reached, the deposited platinum was nevertheless able to occlude the residual gas to an extent sufficient to necessitate the introduction of air every half-hour to reduce the vacuum.

A simple device for extinguishing the spark at a switch on a breaking circuit was shown by Prof. Perry. It is well known that sparking may be stopped by shunting with a condenser, but to absorb the spark which would be produced by a ten-unit dynamo, about sixteen hundred million microfarad condensers would be required. Varley has long ago pointed out that a voltameter acts as a condenser, and Prof. Perry, accordingly, provides a few simple cells, and arranges the switch so that just before contact is broken the cells are put in shunt with the switch. When the handle is moved on, the circuit is broken and discharges into these cells, and on pushing the handle right back the shunt circuit is opened. An industrious historian informed Prof. Perry, on Wednesday last, that the idea was very old, but such inevitable discoveries frequently show that the prior inventor either omitted some practical detail, or, at all events, failed to properly bring his invention before the public.

We are glad to see that the Electrical Trades Section of the London Chamber of Commerce are not allowing the proposals to hold electrical exhibitions at the Crystal Palace and at Taunton to pass unnoticed; but will consider, on Monday next, their attitude in the matter. The fact that such exhibitions, concerning, as they do, practically, one trade alone, are organised without any consultation of a well-established representative body of that trade, goes to prove that they are almost invariably promoted either for the mere profits of the promotion, or as a side-show at a place of amusement. The first electrical exhibition at the Crystal Palace was of great value to trade and to science. The arrangements were well carried out, no charge being made for space. It was thoroughly representative, and formed a valuable supplement to the Paris Electrical Exhibition of 1881, which will for ever remain as the landmark, if not the very starting point, in the history of practical electrical engineering. The exhibition at the Aquarium in 1883 was the occasion of the first display of alternate-current transformers. Nor was the electrical section of the Inventions Exhibition devoid of advantage to the exhibitors and of interest to the intelligent public. The electric lighting department at the Manchester Exhibition of 1887 was remarkable only for one exhibit of an important local firm, and the same may be said for that of Glasgow and other provincial exhibitions. It is one thing to invite contractors to light an exhibition—and very badly they sometimes do it—and another thing to attempt to make a show which shall be representative of the present state of the industry. There was not the smallest desire for the Edinburgh Exhibition. The Chamber of Commerce exacted the condition that the rental for space should be refunded from the profits, and fortunately for the exhibitors this arrangement did not constitute a partnership, and they were not called upon to alleviate the lamentable failure which ensued.

Digitized by Google

YOUNG firms, of course, need but little inducement to make a show, and they are quite right in doing so. Their principals can afford to attend nearly every day, and they generally have, or ought to have, some novelty or speciality to introduce. But we have heard of one solitary advantage which may possibly make it worth while for well-established contractors to put in appearance at electrical exhibitions, and it is this. Numerous local authorities have obtained provisional orders, and do not know what to do with them. They are afraid to carry out the work themselves for they are aware that they know nothing about electrical engineering; and they are afraid to take advice, for they are aware that they know nothing about electrical engineers. With praiseworthy zeal they make excursions to visit various central stations, to interview their managers, and to try to understand the general principles of generation and distribution of electrical energy. Of course, the general principles are the very last matters that they are likely to learn. What they do is to bewilder themselves with a mass of facts unrelated and undigested. In the course of their journeyings they are very likely to go to the Crystal Palace, and it is quite worth the while of a contractor to put himself in the way of such a party But if the presence of the leading firms will make the exhibition a success, they should certainly have a voice in the management.

THE exhibition at Taunton is on another footing, and is chiefly of local interest. Like the exhibition at St. Pancras, it may be of service in showing the residents in the neighbourhood what can be done with electric light and power, and how to do it. There is no need for the extensive display of the wares of important firms. Such a show should stimulate demand for electric supply, and there may be some profits for the promoters, who, in this case, occupy a very legitimate position.

IN our Notes Column will be found a very interesting account of the electric disturbances which have been detected at Greenwich Observatory, caused by the earth currents arising from the operation of the City and South London Railway. The facts that the nearest earth-plate connected with the Observatory was nearly three miles in a direct line from the railway, and that the plates were often found to differ in potential by more than one-third of a volt, show that electric leakage takes place to a very considerable extent. This is due to the fact that the iron tube is connected throughout its length both with the return rails and with the earth. Each section of the tube thus acts as a large earth-plate discharging current into the soil. The proportion of the current which returns to Stockwell in this way may be unexpectedly large, owing to the amount of surface exposed. This distribution of current, too, is favourable to the production of magnetic disturbances, because the return current does not, as in the Deptford cable, completely enclose the outgoing current, as is proved by the existence of these earth currents. Even if the iron tube acts perfectly as a magnetic screen, it becomes circularly magnetised, owing to the unsymmetrical distribution of the current, and may thus cause variations in the intensity of the vertical component of the earth's magnetic force.

THE two Papers dealing with the chemistry of the secondary cell recently read before the Royal Society, abstracts of which will be found in another column, while not bringing us appreciably nearer that bourne of the practical electrical engineer, a really satisfactory storage cell for lighting and traction purposes, elucidate several hitherto obscure points. Having ascertained beyond doubt the presence in the electrolyte of large quantities of persulphuric acid and hydrogen dioxide, Mr. ROBERTSON and Prof. ARMSTRONG are able to explain the efficacy of Mr. BARBER STARKEY'S sodium sulphate treatment, the occasional reversals, the recovery of a rapidly discharged cell after rest, the abnormally high volts after charging, &c. Prof. FRANKLAND'S argument that the sulphate formed during normal charge and discharge *must* be different to the ordinary irreducible white sulphate, since it was not white and was easily reducible, already controverted last summer by Messrs. GLADSTONE and HIBBERT, is also further demolished in the present contribution.

THE claim made by the manufacturers of the substantial switch which is illustrated in our Trade Notes, viz., "a 'large margin of safety' two and a-half times amount of theoretical contact surface," reminds us of the curious anomaly existing in the present custom of denoting the size of a switch by its carrying power in amperes. The three points about a switch are—its general design, its "carrying power," and its price Disregarding for the present such special switches as the two-way and double-pole, in some cases we must have sudden break, in others we need a long break. On many occasions an independent sparking piece is necessary, and a proper design should be chosen for each case. But if we order a 60-ampere switch from one maker he will send us an elaborate piece of mechanism, for which he is justified in charging £2. 10s., while another will send a production which he honestly believes will carry the required current without heating, and asks half-a-sovereign for the modest contrivance. Carrying power depends on the surface in actual contact, and on sectional area of the bridge. The latter should never give trouble. Engineers are familiar with the surfaced joints which WHITWORTH taught them to make. But everyone who has made a surface block for himself, or has even scraped a valve face, knows that as the work progresses the points of contact become more numerous, and, in the best work, lie evenly distributed and close together. But for all that they are points, and there are only a limited number to the square inch, and a very small amount of grinding together will destroy the truth of the plane if only on account of irregularities in the hardness of the metal.

IT is cheaper to put plenty of bearing surface in a switch than to spend work in the accurate surfacing of a small area. If a steam valve has a "full-way" and a sufficient area, we know what it will carry, but if we want a switch to carry 400 amperes it is better for a purchaser to trust to some maker who, having gained practical experience, has a reputation to lose, than to attempt to specify the square inches of bedded contact surface. We were so interested in hearing for the first time of "a theoretical contact surface" that we made inquiries

Digitized by Google

about it from the makers. The result is a little disappointing; we learn that "supposing the current to be carried to be 100 amperes, the section of the switch arm immediately behind the interlocking jaws would be at one square mm. per ampere, say 15mm. broad by 7mm. deep, and the jaws should, of course, have, theoretically, a bearing surface equal to the area of this section. In the switch illustrated, however, this area is multiplied by 2½, or, say, 270 square mm., and when it is considered that each tongue in the switch has at least four bearing points, the margin of safety should be ample." So we learn nothing, after all, about the "theoretical bearing surface" other than that it should be equal to the area of the section. If the sectional area of the arm is satisfactory, but not lavishly designed to carry the current without heating, we should say that the working surface should be, at least, ten times this area; but it is obvious that the switch under consideration has a much better contact surface than the information which we have quoted would lead us to imagine.

"THE ELECTRICIAN" Primers (2 vols.) are now ready. They are intended for elementary readers, and, as considerable care has been devoted in their compilation to precision and clearness, we venture to think that they will prove of considerable assistance to students in grasping the fundamental principles of theoretical and applied electricity.

Cable Extensions.—The duplicate cable connecting Calais with Fano (Denmark), will be laid at the end of July.

Telephone Trunk Wire Extensions.—The Paris-Amiens telephone line, 81 miles in length, was opened to the public on Monday last.

Barnet.—The Local Board have finally determined to discontinue the public lighting of their district by electricity, and to revert to gas, on and after September 1st.

Appointment Vacant.—Applications are invited for the appointment of demonstrator in the department of mechanism and applied mechanics at the University of Cambridge. Further particulars will be found in our advertisement columns.

Society of Arts.—The Council of the Society of Arts, on Wednesday night, gave a *conversazione* at South Kensington Museum. Sir Richard Webster, the Attorney-General, attended by Sir Henry Wood (the secretary), received the visitors, who numbered about 2,000.

Junior Engineering Society. — On the 30th ult., a large party of members of this Society visited the locomotive, carriage, and wagon works of the London, Chatham, and Dover Railway, Wandsworth-road.—The address of the Society's office is now 29, Fentiman-road, Clapham-road, S.W.

Portrait of Major Flood Page.—We have received from Mr. G. B. Black, of 21, Baker-street, W., an excellent lithographic portrait of Major S. Flood Page. Not only is the likeness extremely good, but the artist has caught and has very faithfully rendered a very genial and natural expression.

The Telephone in Berlin.—The subscribers to the Berlin telephone exchange now numbers about 16,000. During the past year nine new lines have come into operation, viz., those to Bankenburg, Gröningen, Lauban, Oschersleben, Osterwiek, Penzig, Quenlinburg, Shale, and Wernigerode.

Electric Mining Machinery.—According to American consular reports from Singapore, gold mining is rapidly developing at Raub, in the Province of Pahang, Malay Peninsula, and the operators are negotiating with American firms for stamp mills, water-wheels and electrical machinery.

The Brillie Meter.—The fact that the Brillié meter, which was awarded a prize in the first competition initiated by the Paris Municipality, should not have even been mentioned in the second has caused some comment, especially as the inventor claims to have considerably improved the meter between times. However, if it be true that the only specimen sent in refused to work, the less said the better.

Royal Society.—The following Papers were down for reading before the Royal Society yesterday:—Dr. J. Hopkinson, "Note on the Density of Alloys of Nickel and Iron;" Oliver Heaviside, "On the Forces, Stresses, and Fluxes of Energy in the Electro-magnetic Field;" Prof. W. G. Adams, "Comparison of Simultaneous Magnetic Disturbances at several Observatories, and Determination of the Values of the Gaussian Functions for those Observatories."

University and King's Colleges.—The hearing by the Privy Council of the petition of University College and King's College for the establishment of a Teaching University in and for London has been fixed for Monday, the 29th inst., at 11 o'clock. Mr. Rigby, Q.C., and Mr. H. Cunynghame have been retained by the petitioners. It is understood that the University of London will limit itself to a watching of the proceedings for the protection of any interests of its own that may appear to be affected.

Dublin.—Work has commenced in connection with the Municipal Central Station. The site is about one-quarter of an acre in extent. The private lighting plant will comprise three 300 H.P. engines, by Coates and Co., of Belfast, each of which will drive a 2,000-volt Lowrie-Hall alternator through rope gearing. The public lighting plant will comprise three 60 H.P. Brush engines and three 55-light Brush dynamos. The cables will be laid in iron piping. The public lights will probably be started in November.

Owens College.—An essay prize of £10 on "The Technical Applications of Electricity" was offered for award in the session 1890-1 by Mr. W. Mather, M.P., and a prize of a similar sum is offered for award by Dr. Edward Hopkinson in the session 1891-2. The subject for the essay in the current session was "Recent Progress in Magnetism," and Mr. Mather's prize has been awarded to Bertram S. Giles, a student in the evening classes of the college. The competition is open to both day and evening students in the Physics Laboratories.

Societe Francaise des Telegraphes sous Marins. — The opening is announced to the telegraphic services of the new cable belonging to the Société Française des Télégraphes sous Marins, between Puerto Plata and Martinique. A new cable (the Haïti line) has also been opened in connection with Martinique, Guadeloupe, and Dutch Guiana, with a reduction of 2s. 6d. on the present tariff. The Société des Télégraphes sous Marins has just opened a new station at Cape Haïtien (Haïti). The head office of the Society is at 32, Rue Caumartin, Paris.

Sir Frederick Abel.—The Albert Medal of the Society of Arts for the present year has been awarded by the Council to Sir Frederick Abel, in recognition of the manner in which he has promoted several important classes of the arts and manufactures by the application of chemical sciences, and especially by his researches in the manufacture of iron and of steel; and also in acknowledgment of the great services he has rendered to the State in the provision of improved war material, and as chemist to the War Department.

Electrolytic Galvanising.—According to a patent just taken out in Germany, by Schaag, of Berlin, and a Baden firm, the following is a method of obtaining, by way of electrolysis, an adherent deposit of zinc:—Salts of magnesium and mercury are added to the ordinary bath. The addition of magnesium increases the conductivity without increasing the acidity of the solution. The deposited zinc contains a minute trace of magnesium, which renders it hard and adherent. The mercury is said to ensure a regular white deposit.

The Electric Light at the British Museum.—Alterations and additions are being made to the electric lighting apparatus at the British Museum. After July 4th next it is proposed to throw the whole of the Museum open to the public in the evenings, instead of, as has hitherto been the practice, admitting visitors to the eastern and western galleries on alternate nights.

Digitized by Google

This is a step in the right direction, but a still greater convenience to the public would be, as we have already pointed out, the throwing open of the Museum during the entire day from 10 a.m. till 10 p.m. The closing for a few hours until the reopening at 8 is probably one reason for the comparatively scanty attendance in the evenings.

The Chelsea Electric Lighting Provisional Order.—The Bill embodying this order came before a Select Committee of the House of Commons on Monday. Sir S. Northcote presided, and the other members of the Committee were Mr. F. T. Barry, Mr. J. Wilson, and Mr. E. Kuatchbull-Hugessen. Mr. Pember, Q.C., who appeared for the promoters (the New Cadogan Company), said it had been arranged with the opponents (the London and Chelsea Companies) that the order should go unopposed on the understanding that the opponents were not to be prejudiced by what had occurred in that House. If a settlement was not arrived at, the opponents would be perfectly free to oppose the order in the other House, and he undertook to make no reference whatever to the present proceedings. The order, therefore, passed unopposed.

London Chamber of Commerce.—A meeting of the committee of the Electrical Trade Section will be held on Monday, the 22nd inst., at 3 p.m., to consider the following agenda:—(1) Correspondence: letter from one of the witnesses who attended at the Board of Trade in the matter of the inquiry into electrical standards; overhead wires; letter as to Prof. Mengarini, of Rome, being about to transmit 2,000 H.P. from Tivoli to Rome at a pressure of 5,000 volts along bare wire. (2) To consider the desirability of placing wires underground in future. (3) To consider the attitude of the Electrical Section towards the proposed Crystal Palace Electrical Exhibition and also the Taunton and South-West of England Electrical Exhibition. (4) Frankfort Exhibition: to consider whether a party from the Section should visit the Exhibition from, say, August 5th to the 15th.

The Proposed Pacific Cable.—The following extract is from the *Shanghai Mercury* of May 1, 1891. Up to the present time the greatest depth from which a submarine cable has been recovered is 2,720 fathoms:—"The survey made by Rear-Admiral Belknap, U.S.N., of the North Pacific, demonstrates that the proposed great circle for a submarine cable is not feasible. His soundings indicate the existence of a trough or basin or of extraordinary depth and extent, along the east coast of Japan and the Kurile Islands, and under the Kuro Siwo, or Japan or Black Stream. The basin exceeds any similar depression yet found in any other regions of the great oceans. In a run of 30 miles, after leaving the coast of Japan, the waters deepened more than 1,800 fathoms, and upon the next cast of the lead the wire broke, after 4,643 fathoms had been run out without bottom having been reached. Thermometers, specially constructed for deep sea sounding, were wrecked by the unprecedented pressures. The depth of the deepest cast—five miles and a quarter, the deepest water yet found—is sufficient to hold two mountains as high as Japan's great Fusiyama, one on the top of the other, and then the summit of the highest would be nearly two-thirds of a mile under water. This region of the Pacific has been named the 'Tuscarora Deep,' after the vessel that made the survey."

The Electric Transmission of Power from Tivoli to Rome.—The first idea of transmitting power by means of electricity from Tivoli to Rome was due, says M. F. Cardarelli in the *Giornale delle Communicazioni*, to the Società per le Industrie Idrauliche, and the large hydraulic works carried out with a view to the execution of the original plans are now being made use of in connection with the scheme of the Società Anglo-Romano per la Illumazione di Roma. This scheme involves the transmission to a distance of 18½ miles, and at an electrical pressure of 5,000 volts, of some 2,000 H.P. The motive power is obtained from the Anio, whose waters, after having been utilised by various industrial establishments, will be collected in an aqueduct, 1¼ miles long, and conducted to the turbines, where a head of 165ft. and a flow of 770 gallons per second are available. The generating plant is to consist of six horizontal 360 H.P. Girard turbines, each coupled direct to a 300 kilowatt (6,000 volts × 50 amperes) Ganz alternator, and three 50 H.P. turbines coupled to exciters. The line is to be run overhead, extreme care being taken to make the supports strong and to insulate them from the soil. The poles are of iron, and are some 100ft. apart, the four bare copper conductors, made by the Società Metallurgica of Leghorn, being ranged one underneath the other, at an average height of 28ft. from the ground. Two circuits, composed of 19/12 stranded cable, will be run, the total resistance of each circuit being 10 ohms. The insulators, made by the firm of Giorni, are of the Johnson and Phillips oil pattern, modified so as to permit of rapid cleaning of the oil cup; an essential feature on this line, which is infested with insects. At Rome, a transformer sub-station is being erected near the Porta Pia, where the pressure will be reduced from 4,000 to 2,000 volts, and the current distributed at that pressure to transformers in consumers' houses by means of Siemens concentric cables. The initial pressure of the alternators is 6,000 volts, and, at full load, 1,000 volts will be lost in the armature, and 1,000 volts in the line, the pressure at the Rome transformer sub-station being kept constant by automatically varying the pressure at the dynamo terminals. It is proposed to run the dynamos in parallel. At Tivoli there will, therefore, be a variable current and a variable potential, while at Rome there will be constant potential and variable current for the private lighting network, and constant current and variable potential for the street lamps.

Earth-Currents and the City and South London Railway.—A well-marked case of interference with the earth-currents recorded at the Royal Observatory, Greenwich, due apparently to the working of the City and South London Railway, has been communicated to *Nature* by Mr. William Ellis. For years past a continuous photographic register of earth-currents has been maintained at the Observatory. There are two circuits. For one circuit the earth-plates are at Angerstein Wharf (A.W.), on the Thames, near Charlton, and at Lady Well, Lewisham (L.W.), three miles distant; for the other circuit the earth-plates are on Blackheath (B.), and at the North Kent East Junction (N.K.E.J.) of the South-Eastern Railway, two and a-half miles distant. The earth connection is in each case made by an independent copper plate. The azimuth of the A.W.-L.W. line, reckoning from magnetic north towards east, is 50°. Towards the end of last year anomalous appearances began to be observed in both of the earth-current registers, and for some months past these interruptions have settled down into a regular order. A continuous vibration of the registering needles commences shortly before 7h. in the morning, and goes on all through the day, terminating shortly after 11h. in the evening. This went on for several months on week-days only, ceasing on Sundays. But on Sunday, April 5, and on every succeeding Sunday to the present time, the interference has been experienced also on a portion of the Sunday, commencing at about 1h. p.m., and terminating usually at 10h. p.m., or shortly afterwards. Various experiments were made with the view of discovering the cause of these anomalous appearances, but without definite result. Quite recently, Mr. Leonard, the telegraphic superintendent of the South Eastern Railway, suggested that the exceptional appearances were most probably due to the influence of the Electric Railway. A comparison being made between the observed times of interference with the earth-current registers, and the published times of running of the trains, it was found that these were simultaneous. The line of the Electric Railway runs from about north-east to south-west magnetic, or, more accurately, the azimuth of the line, reckoning from magnetic north towards east, is about 50°. The nearest earth-plate to the railway is the N.K.E.J. plate, which is distant from the railway, in a perpendicular direction from it, about two and a-half miles. The correspondence so far as the comparison goes is complete. During the periods of interference the registering needles at the Observatory are in continual vibration. Whether the impulses are in one direction only or in both directions, and what is their frequency, cannot be readily determined from the registers. Eye observation of the needles may, perhaps, reveal something to us on these points. The abnormal excursions of the needles indicate a change of potential varying from a small fraction of a volt to perhaps the one-third of a volt or more.

MAGNETISM IN IRON AND OTHER METALS.*—XLIII.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 154.*)

§ 149. **The Magnetic Circuit.**—For many purposes, the most convenient way of treating the magnetisation of iron is to consider what is happening at a point within the metal. This is, in fact, the basis on which our exposition of the subject in earlier chapters has been developed. We have learnt to conceive of a magnetic force H acting in a definite direction at the point considered, and also of a magnetic induction B at the point. If the material is isotropic, and has no residual magnetism superposed upon the magnetism which H induces, the direction of B is the same as that of H. The ratio of B to H is the permeability μ. Passing from point to point of the metal, we may in certain cases find that H and B do not change; more generally they do change. Thus, in a uniformly wound circular ring magnet, of uniform section and material, H has the same value at all points on any circle co-axial with the ring. In a long straight bar magnet the value of H is nearly uniform, except in the neighbourhood of the ends. Whether H be uniform or not, it has a single definite value and definite direction at each point, and the same thing is true of B. At points where there is no magnetisable substance, the value and direction of B are the same as the value and direction of H; this applies, for instance, to all points in air. The value of H at any point is determined by finding the resultant of the force produced at that point by (1) all the conducting circuits, and (2) all the free magnetism in the neighbourhood; that is, by finding the resultant mechanical force which would be felt by a unit pole of free magnetism if placed at the point in question.

From this point of view, when our object is to discuss the magnetisation of a piece of metal, we have first to consider what is the value of H at each point within the piece. Thus, in dealing with a uniformly-wound ring, we treat the case by finding that the magnetic force H is $4\pi C n$, when C is the current and n is the number of turns in the magnetising coil per centimetre of the ring's length. And in dealing with a uniformly-wound rod, we find H to be $4\pi C n$ *minus* a certain quantity which is due to the free magnetism at and about the ends, and which becomes unimportant when the rod is exceedingly long. Many problems in magnetism are best treated in this way, namely, by considering the condition of things at individual points in the magnetised piece.

But there is another way of regarding the matter, not in the least antagonistic to this, but sometimes more convenient. Instead of thinking about what happens at individual points, we may view the the magnetism of the piece as a whole, by considering what is called the *magnetic circuit*. This is the method which has been applied by J. and E. Hopkinson† and by Kapp,‡ to pre-determine the magnetism of dynamos. Its applicability to dynamos and transformers give it peculiar importance on the practical side; moreover, apart from that, the conception of the magnetic circuit has much interest as an alternative standpoint from which the facts of electro-magnetism may be viewed, and as suggesting methods of experimental enquiry.

§ 150. **Tubes of Magnetic Induction. Definition of Magnetic Flux and of a Perfect Magnetic Circuit.**—The lines of magnetic induction, as has been already pointed out (§ 14) are continuous through space, whether the space is filled with magnetisable or non-magnetisable substance, or partly with one and partly with the other. There is no discontinuity of B—no sudden change in its value or direction—when the lines pass from metal to air or from air to metal. Each line of induction is a continuous curve; moreover, it is a *closed* curve—that is to say, if traced along its whole course it returns to the point at which the tracing began. We may conceive of all space as filled with sheafs of lines of induction, or (which is the same thing in other words) as partitioned into tubes, the boundaries of which are formed by lines of induction. Every such tube contains a number of lines of induction, and if we follow the tube along its whole length until it returns into itself we find everywhere the same number of lines of induction in it. We may take a large sheaf or a small one to constitute the tube, but, whatever be the number of lines in it to start with, the same number is present at every part of its length. Its cross section may vary; the tube may widen or contract from place to place along its length, but if this happens it is by the lines spreading out or coming closer; the number of the lines does not change. At places where the induction B is strong, the tube is contracted; at places where the induction is weak, the tube is expanded. But if we take any cross sections (s) of the tube perpendicular to the direction of B, the product $B s$ (or to be more exact, the surface integral $\int B\,ds$ taken over the section, since B is not necessarily the same over all parts of s*) is a constant quantity for any one tube. At any sections s and s', the values of the induction B and B′, are such that $\int B\,ds = \int B'\,ds'$. It is convenient to have a name for this constant quantity, which is the whole number of lines of magnetic induction in the tube. Following the usage of several recent writers we shall call it the *magnetic flux* in the tube.

Any tube of magnetic induction, considered as a whole—that is to say, considered as a circuit which returns into itself—may be called a *perfect magnetic circuit*. The perfect magnetic circuit is analogous to a perfectly insulated electric circuit conducting a current. The lines of induction correspond to lines of flow of current. The cross-section of the conductor may vary from place to place, but the current density varies in inverse proportion to the cross-section and the product of current density into area of cross-section—which is simply the whole current—is constant at all sections, just as the flux $B s$ is constant in the perfect magnetic circuit.

§ 151. **Imperfect Magnetic Circuit.**—An imperfectly insulated electric circuit allows some of the lines of flow to enter it or to leave it through the sides. We have the magnetic analogue of this when we have to deal with the magnetisation of a material ring of any form, in which the sides of the ring do not coincide with the sides of a tube of induction. This means that there are places where some of the lines of induction leak out, so to speak, from the substance of the ring through its sides into the surrounding medium. It is often convenient, especially when the greater part of the whole flux remains in the ring, still to speak of such a ring as a magnetic circuit. We shall distinguish it from a true tube of induction by calling this leaky ring an *imperfect magnetic circuit*. It is imperfect, inasmuch as it leaves out those portions of the surrounding medium through which some of the lines of induction stray, the inclusion of which would be necessary in order to make the tubes of induction complete. Examples of imperfect circuits will be given presently.

§ 152. **Line Integral of Magnetic Force, or Magneto-Motive Force.** We have now to express the relation of the magnetic flux in a perfect magnetic circuit to the whole magnetising agency acting on the circuit, just as in a perfectly insulated electric circuit we express the relation of the current to the whole electromotive force that is operative throughout the circuit.

We have in the magnetic circuit an agent to which (when we are dealing with induced magnetism) the magnetic flux is due, which corresponds to the electromotive force of the electric circuit. To this agent Bosanquet† has given the name of *magnetomotive force*.

One way of defining the electromotive force of an electric circuit is to say that the electromotive force is the amount of work which would be done in carrying unit quantity of electricity completely round the circuit.

In the same way we may define the magneto-motive force of a magnetic circuit as the amount of work which would be done in carrying a unit magnetic pole completely round the circuit. At any point of its path the unit pole is acted on by a mechanical force which is equal to and in the direction of the magnetic

* All rights are reserved. † *Phil. Trans.* ‡ *Jour.* Soc. Tel. Eng.

* The cross section, over which this integral is calculated, is taken so that every element of the surface is perpendicular to the lines of B which cut it. Thus, if the lines of B in the tube are not parallel, the surface forming the cross section will be curved.

Digitized by Google

force H, and it is against this mechanical force that the work is done.

Another name for the same quantity is the *Line Integral of Magnetic Force*, taken round the circuit.* Conceive the path along which the unit pole is moved to be made up of a great many short pieces, any one of which is so short as to be sensibly straight and to have a sensibly uniform value of H from end to end of it. Let the length of any short piece be δl, and let its inclination to the direction of H be ϵ. Then the work done in moving the unit pole along this short piece of the path is measured by the product of the length of the path (δl) into the component of the force H along the path; that is to say, it is $H \cos \epsilon \delta l$. The whole work done in moving a unit pole along the path is got by summing up the work done at each short piece; that is to say, it is $\Sigma H \cos \epsilon \delta l$, or $\int H \cos \epsilon \, dl$ when the elements into which the path is divided are indefinitely numerous and indefinitely short. The expression $\int H \cos \epsilon \, dl$ is the line integral of the magnetic force along the path.

We may integrate the magnetic force in this manner along any curve whatsoever. The term line integral of magnetic force is not in the least restricted to cases in which the integration takes place round a magnetic circuit. Let the path through which the unit pole is supposed to be carried, extend through space in any manner the line integral, namely, $\int H \cos \epsilon \, dl$, measures the work done in carrying the pole along it.

In cases where the direction of the line coincides at all points of its course with the direction of H, $\cos \epsilon$ is everywhere unity, and the expression for the line integral of the magnetic force becomes $\int H \, dl$. This is generally† the case when the line in question is a line of magnetic induction, that is to say, when the line integral of magnetic force is calculated for a perfect magnetic circuit.

§ 153. **Value of the Line Integral of Magnetic Force.**—When the integration is extended all along any closed curve, in other words, when the imaginary unit magnetic pole makes a complete journey along any path which returns into itself, it may be shown that the line integral of magnetic force admits of very easy calculation. If the curve along which it is reckoned does not thread its way through any circuit in which a current is flowing, then the value of the line integral of magnetic force along the closed curve is zero. If the curve does thread its way once through a circuit in which a current C is flowing, then the value of the line integral of magnetic force along the closed curve is $4 \pi C$; and if the curve threads its way N times through such a circuit, the value of the line integral is $4 \pi C N$. For, example, if the line along which the line integral of magnetic force is reckoned is any closed curve which is threaded through the interior of a coil of N turns, the line integral is $4 \pi C N$, for the line is interlinked with the current circuit as many times as there are turns in the coil.

The principle that the line integral of magnetic force is equal to $4 \pi C N$, when taken along any closed curve is an absolutely general one. It is true whatever be the position and direction of the curve, whether it lie along a line of force or no, and whether it lie wholly or partly in a non-magnetisable substance, such as air, or wholly or partly in a magnetisable substance such as iron. If the closed curve threads through more circuits than one, the sum of the terms $4 \pi C N$ is to be taken.

Two simple cases will serve as instances. Suppose we have a uniform solenoid of n turns per centimetre, and l centimetres long. Let the ends be bent together so that it forms a closed ring. The length of a closed curve in the centre of the solenoid is l. The magnetic force H is uniform all along that line, and is equal to $4 \pi C n$. The value of $\int H \, dl$ is, therefore, $H l$ or $4 \pi C n l$, or $4 \pi C N$, since N the whole number of turns $= n l$.

Again, consider the magnetic force around a long straight conductor (the remainder of the circuit lying so far off as to be uninfluential) and integrate $\int H \, dl$ along the circumference of a circle of which the conductor is axis. The force at any distance r from the axis of the conductor is $\frac{2C}{r}$. This is uniform throughout the circular path, and is in the direction of the path. The length of the path is $2 \pi r$. The line integral of magnetic force round the path is, therefore, $\frac{2C}{r} \times 2 \pi r$ or $4 \pi C$. In this case the path along which the line integral is taken is interlinked with the circuit only once.

The principle set forth in this paragraph may be stated thus:—The line integral of magnetic force along any closed curve is equal to 40π, or 125·66, into the number of *ampere-turns* in the coil or coils which are threaded by the curve.

(*To be continued.*)

* Maxwell, "El. and Mag.," Vol. II., § 401.

† Namely, when the medium is isotropic and has no residue of previous magnetisation in a direction inclined to the direction of H.

STANDARD CELLS.

At a recent meeting of the Franklin Institute, Mr. Carl Hering described a modified form of Daniell standard cell, devised by him with a view of having it always ready for use. It consists of two bottles containing two liquids with their respective electrodes, the bottles being connected at their bottom by a small tube with two stopcocks, the portion of the tube between the two cocks communicating directly with the air. By this means the liquids, which mix at their contact, are allowed to drain off as rapidly as they mix. To prevent too rapid a flow some filter paper, cotton, or asbestos, is packed into the tubes. The intermediate tube may be drained completely; there is always a film of liquid sufficient to answer for a contact if the cell is used on open circuit. The internal resistance of the cell is naturally high (10,000 to 20,000 ohms). The E.M.F. of a Daniell, according to Dr. Fleming, is 1·105 true volts at 16°C., when the specific gravity of the zinc solution is 1·2, and that of the copper is 1·2, when the zinc is amalgamated, and the copper is freshly electro-plated with an untarnished, salmon-coloured coating, having no brown spots. The solutions and metals must be perfectly pure, and the solutions made with distilled water and filtered, being diluted to the required amount after filtration. Such a cell may be kept standing indefinitely, and is always ready for use. The only remaining objection is that the copper electrode does not remain clean. It should be freshly electro-plated, before using, which is readily done in a test tube with a platinum anode. To overcome this, Mr. Carl Hering suggests the amalgamation of the copper, and when not in use to keep it in a tube of mercury.

In experimenting with this cell a curious phenomenon was noticed. It was found that the slight pressure produced in the bottles by inserting the corks at the top, produced decided differences in the E.M.F. of the cell; this was noticed for each of the liquids, and was different in the two cases. It was, therefore, found essential to use a cork with a hole through it, so as to prevent this pressure from being exerted.

Writing in the New York *Electrical Engineer* of June 3rd, Prof. Cahart states that the effect of pressure upon E.M.F., mentioned by Mr. Carl Hering, is not quite new, as may be ascertained by referring to Tommasi's "Pile Electrique," p. 364. The suggestion that the necessity of freshly electro-plating the copper electrode every time it is used might be avoided by amalgamating the copper, would, he says, be a very disappointing one to put into practice; for amalgamated zinc and amalgamated copper give a much smaller E.M.F. than the normal one of the Daniell cell. Moreover, it is quite as important that the zinc should be as free from oxide as the copper. Considering these facts, and the extreme difficulty of preventing admixture of the two sulphates, whoever has had the use of a good Clark cell will never, he thinks, be willing to employ the Daniell, except in case of necessity.

The high temperature coefficient of the Clark cell can hardly be urged against it now, since its value has been reduced to half its former one. As an indication of the permanence and reliability of the Clark cell, Prof. Cahart quotes some figures obtained by him relating to a Clark standard made four years ago after Lord Rayleigh's directions, to two more made two months ago, and to a Rayleigh cell, four years old, put up in a wide-mouthed bottle, which had been used promiscuously by perhaps one hundred students in the laboratory. A

Digitized by Google

comparison of the four cells on April 1 gave the following relative value of the E.M.F., the numbers given being the ohms required to effect a balance by the Rayleigh method of comparison: old Rayleigh cell, at 20·5°C., 9,118; first new Raleigh cell, at 20·5°C., 9,118; second new Rayleigh cell, at 20·5°C., 9,116; cell in bottle, at 20·5°C., 9,117. One week later, at 12·7C., the first three gave 9,179, 9,176, 9,176 respectively. The other was not compared.

In conclusion, Professor Cahart says:—"I have 10 cells, of my own special make, in a rack by themselves, that never, I think, show an extreme difference among them of more than five parts in ten thousand. I consider Clark standard cells quite indispensable in an electrical laboratory."

MAVOR AND COULSON'S METHOD OF CONCENTRIC WIRING.

The concentric system of electric light wiring for buildings and ships is now attracting a good deal of attention. Notwithstanding several advantages which it offers over double wiring in simplicity and security, the prejudices of insurance companies have, in many cases, blocked the way to its introduction. While the advantages of concentric wiring for land work are great, they are even more conspicuous for ship work. The facility with which this system of wiring can be made thoroughly water-tight is the strongest possible argument in its favour for ship use. The British Admiralty have partially recognised this, and have adopted lead sheathed conductors for electric lighting and also for electric bell circuits, torpedo and gun-firing circuits, &c.

The concentric watertight cables used by Messrs. Mavor and Coulson, of Glasgow, for ships' work, are for the most part manufactured by the Fowler-Waring Company. They are lead

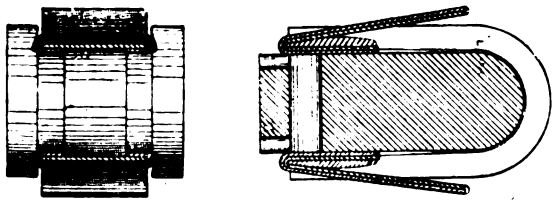

Fig. 1.—Porcelain Fuse Block with Copper Springs held in Undercut Grooves.

sheathed, and are protected by an armouring of iron wires laid over the lead on a cushion of jute. In the case of branch wires in cabins, the iron sheathing is dispensed with, and the outer conductor is formed of a copper braiding laid on under the lead tube. The principal object of this braiding is, in the case of short circuit, to carry sufficient current to burn out the fuse without fusing the lead sheathing of the conductor. The smallest size of conductor used is No. 14, S.W.G., and this carries current for eight lamps.

These branch conductors, each carrying a group of eight lamps, radiate from distributing boxes, which contain a fuse, and, if desired, a switch, for each group. The distributing boxes are of cast iron, and each contains from four to ten fuses, mounted on a slate base, and is thus the centre of distribution for from 30 to 80 lights. The main conductor from the dynamo or main switch board enters the fuse box at a tail cast in the side of the box. The core of the cable is carried into the terminal block on the distributing bar. The end of the insulation is treated with water-tight compound, and a soldered joint is made between the tail and the lead sheath of the cable, the iron armouring being also bound to the tail. Each branch wire is led through a similar tail in the top of the box, a soldered joint being made between the tail and the lead sheath of the conductor. The cover of the box is of plate glass, in a cast iron or brass frame, screwed against a rubber joint.

The fuses (Fig. 1) are tin foil strips mounted on porcelain blocks, with copper contact springs. They are all interchangeable and of uniform size.

The advantages of these distributing boxes in affording facilities for testing are obvious. All branch conductors are of the same size, viz., No. 14 S.W.G., and this size is carried into the base block of every fitting and into every switch. The base blocks to which the fittings are fixed are of cast brass. In every case the lead sheathing is soldered to the tail, and the end of the insulation of the conductor protected against moisture. The end of the central conductor is secured under a small disc, which is mounted on a slate base. Against this disc the contact terminal in the fitting is pressed by a buffer spring, when the fitting is screwed into the base.

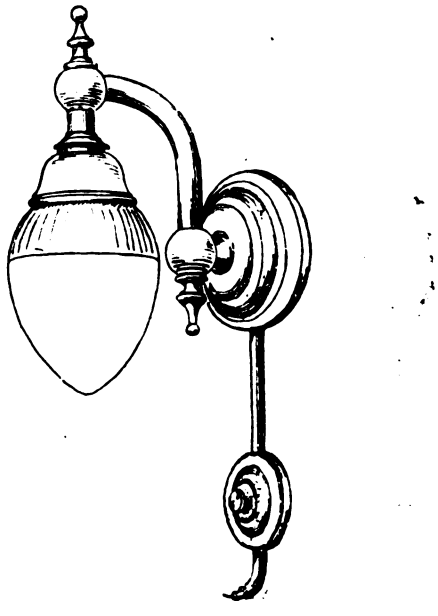

Fig. 2.—Fitting with separate Switch.

The switches, where practicable, are combined with the fittings, but when separate switches are required that shown in Fig. 2 is used. The box is of cast brass, with projecting tails, to which the lead sheathing of the conductors is soldered, the central conductor being also soldered to two terminal studs fixed in a slate base in the box. The switch shown in section in Fig. 3 is a double-threaded quick screw working in the cover, pressing a small insulated disc D on the contact studs C C. A small spiral spring S raises the disc off the contacts when the pressure of the screw is released. The fittings are wired with

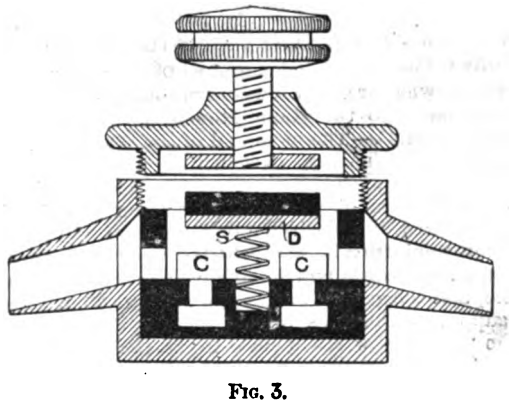

Fig. 3.

S = Spiral spring. D = Brass Disc. C C = Contact studs.

central contact wiring before being sent on board, and are all interchangeable in relation to the base blocks, to which they are screwed. A separate main is led direct from the main switchboard to each distributing box, and in large vessels, where transverse bulkheads divide the ship into several water-tight compartments, a distributing box is provided in each compartment, and each may be controlled independently from the engine-room. Where joints are necessary in branch conductors a lead sleeve is laid over the insulation, and soldered to the sheathing of the

Digitized by Google

conductor. The special features of such a system of wiring are:—1. There are no joints in the main cables. 2. The number of joints in the branch conductors is reduced to a minimum. 3. The fuses are grouped together in readily accessible distributing boxes. 4. The branch conductors being all of uniform size, the fuses throughout are interchangeable. 5. Switches and fuses are enclosed in watertight cast brass or iron boxes. 6. The lead sheathing of the conductors is soldered at every junction with switches, fuses, or fitting bases, thus insuring an absolutely continuous system.

The methods described above are the outcome of many years' experience of ship wiring, during several of which Messrs. Mavor and Coulson had the co-operation of their late partner, Mr. J. D. F. Andrews. The result as regards mechanical strength, neat appearance, and the high standard and reliability of the insulation attained have ensured the confidence of shipbuilders and shipowners who have had experience of it. Messrs. Mavor and Coulson have carried out several important land installations in Scotland during the last few years with concentric wiring, and would have adopted it much more widely but for the determined opposition of insurance companies, some of whom they have taken much pains to convert. It is to be hoped that insurance companies, who are really only interested from a fire-risk point of view, will soon overcome their prejudices and realise that the concentric system of wiring, when properly carried out, is much more safe than double wiring.

ELECTRICAL COMMUNICATION WITH LIGHTHOUSES.

On Friday last, at the offices of the Board of Trade, Sir Michael Hicks-Beach received a deputation from the Associated Chambers of Commerce of the United Kingdom, on the subject of telegraphic communication with lighthouses. The President was accompanied by Sir Henry Calcraft, K.C.B., Sir George Nares, Mr. Trevor, C.B., and Mr. Walter J. Howell, Private Secretary. The deputation from the Chambers was accompanied by the following Members of Parliament:—Colonel Hill, Mr. F. Roe, Mr. Colman, Mr. Manfield, Mr. C. T. Murdoch, Sir George Elliot, Sir E. J. Reed, Mr. F. B. Grotrian, Mr. Isaac Wilson, Mr. Herbert Gladstone, Sir Albert Rollit, Mr. L. Lyell, Mr. T. Lea, Mr. P. Esslemont, Mr. T. B. Potter, Lord Ebrington, Dr. Farquharson, and Mr. Arnold Morley.

Colonel HILL, in introducing the deputation, said he would read the following resolution of the Chamber of Commerce, and also present the following memorial from that body. The resolution was as follows:—"That in the opinion of this Association it is most important that, in addition to the coastguard stations, the lightships, and lighthouses, both on the mainland and on adjacent islands, such as Lundy Island, be placed in telegraphic communication with the general telegraphic system, and that the Executive Council be requested to take such steps as they may consider expedient to carry this resolution into effect." The deputation came for that purpose. The memorial which he now presented had been drawn up with care, and it was as follows:—"Communication with Lighthouses—To the Right Honourable Sir Michael Hicks-Beach, Baronet, M.P.—The memorial of the Associated Chambers of Commerce showeth, that, inasmuch as a sacrifice of life and property takes place yearly on the coasts of the United Kingdom, owing to the absence of prompt information of ships being in distress or wrecked, it is desirable that a system of telegraphic or telephonic communication be established between coastguard and lifeboat stations, lighthouses and lightships, so far as may be possible or desirable, and the general telegraphic system. Your memorialists would in support of the need of this communication refer to the case of the 'Schiller' wrecked close to the Bishop Lighthouse in 1875, when 331 lives were lost; the lighthouse-keepers saw the wreck, but their signals could not be heard nor seen from the shore. The coroner's jury at St. Mary's, Scilly, found that had the light-keepers been able to communicate with the shore the whole 331 lives would have been saved. Again, in the case of the 'Agnes Jack' off Port Eynon, Swansea, 17 men were lost, after clinging to the masts of their ship for five hours. Had there been telegraphic or telephonic communication with Swansea they would certainly have been saved. And more recently, in 1889, to the case of the ss. 'Lymington,' which was wrecked in February within sight of the Lighthouse at Bull Point, with loss of her crew of eight men, who would all have unquestionably been saved had the lighthouse-keepers been able to telegraph to Ilfracombe for assistance. It would be easy to multiply such cases, but it is well known that they occur from time to time on our coasts. Each minute saved in rendering assistance at shipwrecks is frequently a question of life and death. Your memorialists would point to the fact that in France, Denmark, Norway, Holland, Sweden, Canada, and the Cape, the lighthouses are connected by telegraph and telephone with the general system of those countries. It happens frequently that disabled ships drift helplessly in the sight of rock lighthouses in positions dangerous not only to themselves, but to navigation in general; assistance might speedily be obtained from steam tugs and of neighbouring ports if the lighthouse-keepers had the means of telegraphing for it. During the recent gales, 70 lives are believed to have been lost in the immediate neighbourhood of the Start Lighthouse. Some of the wrecks were seen as they occurred; but the lighthouse-keepers had no means of communicating with the rocket apparatus stations except by messenger. Assistance did not arrive in time to save any of these lives. Your memorialists would urge that the lighthouses on all salient points of the coasts should be put into communication with the telegraph system of the country either by telegraph or telephone. Your memorialists suggest that if such a service of communication were established and administered through the agency of the Post Office a considerable revenue might be raised by means of a scale of charges, which might be made to depend to some extent on the nature of the services rendered to disabled ships, together with fees for the conveyance of ordinary information. Your memorialists would point out that, in the time of war, our outlying rock lighthouses might render the greatest service in conveying information to or from Her Majesty's Navy respecting the movements of an enemy. Your memorialists would urge that if it be possible at once to establish the complete system of communication desired, a commencement might be made without delay at such important points on the coasts as experience may show to be essential. Given under the common seal of the Association this 12th day of June, 1891. Edward S. Hill, President, 1, Great College-street, Westminster, S.W." It was, first of all, thought that this being a matter of national importance involving several public departments, they ought to have approached the Prime Minister upon the subject, but Lord Salisbury suggested that they should come to the Board of Trade, and they were pleased to do so, having a grateful recollection of the kindness, courtesy, and patience of Sir Michael. It could not be denied that disastrous wrecks occurred from time to time around the coasts which were attended with loss of life and a considerable loss of valuable property. The saving of life and property when jeopardised in this manner almost always depended upon the promptitude in which appropriate assistance could be rendered. That assistance existed in all their ports in the shape of steam-tugs and lifeboats at various stations outside the ports, with rocket apparatus and other means. But what was required was some means of letting these stations know that necessity existed for their help. They had a post of observation in their lightships, rock lighthouses, and lighthouses ashore, and in the various coastguard stations which surrounded the coast, but they had no means of communication with them. They asked that the deficiency should be supplied, and that those posts of observation should be placed either in telegraphic or telephonic communication with the telegraphic system of the country. There might be difficulties, which, however, might not be insurmountable. In carrying this out an estimate had been made that £100,000 would suffice, but whether that estimate was correct or not he would say that even the expenditure of a very much larger sum would be justified if the lamentable loss of life could be prevented. It would be a great advantage to the commerce of the country that they should have accurate and prompt information of the movement of vessels, and in time of war it would be most invaluable both to the naval and military authorities. Other countries enjoyed these facilities, and a great country like ours should not be behind-hand. Sir Michael had suggested that they should give a list of the names of certain points on the coast where communication with the telegraphic system of the country was most needed, and those points were:—St. Agnes, Scilly, Start, St. Alban's Head, Dungeness, North Foreland, Cape Clear, Flamborough Head, Rattray Point, South Stock, St. Anne's and Lundy Island. Sir Michael might not be able to carry out all this immediately, but a commencement might be made in the national interest, and a saving of life and property might be effected and correct information might be obtained both for commercial, naval, and military purposes.

Sir ALBERT ROLLIT advocated the necessity of having the Spurn Light in communication with the shore.

Mr. BAYLEY, of Plymouth, gave several instances; the case of the "Schiller," the "Lymington," the "Agnes Jack," and the "Mexico," where, if there had been communication with the mainland, the lives of their crews would have been saved.

Captain POMEROY (Cardiff) having spoken,

Mr. JOHN R. WIGHAM (Dublin Chamber) said he came, at the request of the Dublin Chamber of Commerce, to ask Sir Michael to give his best attention to the memorial which had been handed in. The view of the Dublin Chamber was that the whole of the

Digitized by Google

dangerous coasts of the country should be connected together, and put in telegraphic communication with the lighthouses, so that in the event of shipwrecks assistance might be obtained. The Commissioners of Irish Lights, with whom the Dublin Chamber has been in communication, had informed them that it would be an incalculable advantage if telegraphic communication could be made over the great headlands, so that the different stations could be put in direct communication with the telegraphic system of the country. The Chamber of Commerce were interested in what was useful for the shipping interest, but they were also interested in the more important question of the saving of life; and on the general question he would say that the mercantile community of Ireland, and especially that part of it represented by the Chamber of Commerce in Dublin, were exceedingly strongly in favour of the memorial, and anxious that some steps should be taken to remedy the disastrous state of things that existed at present.

Mr. Esslemont, M.P., Mr. Grotrian, M.P., Mr. Bulteel (Plymouth), and Mr. Lyall, M.P. (who advocated the necessity for further provision being made for the north and west coast of Scotland), having spoken, Sir Michael Hicks-Beach replied as follows:—I should like, if I could, to be quite clear as to that part of the subject with which it is possible for me to deal. I do not understand that you come to me to-day to suggest that this communication should be established for the purpose of trade. Lloyds, of course, now undertake the signalling for that purpose, which is fair for all those whom it concerns, and I think it ought to be so. And, in addition, there is the strongest evidence on the part of those who have inquired into the subject and are well qualified to speak as to the impolicy, at any rate, of entrusting such duties to men in lighthouses who have pretty well enough to do in the ordinary way to look after the lights. If you take up their time which ought to be occupied in that way, for the purpose of signalling ships for trade purposes, I think it would be a great evil. All that you ask me to consider to-day, I understand, is the question so far as affects the saving of life in cases of wreck. Then I would ask you in turn to understand that I really can have nothing to do departmentally with the matter so far as it affects the Coastguard Service. The Coastguard are, of course, under the Admiralty, and any fresh duties to be imposed upon them would be imposed with the consent of the Admiralty, and under rules to be made by the Admiralty. The expense connected with the Coastguard stations and the telegraphic service generally is, I think, one which ought to be borne, if it were done, by the Treasury, and therefore you should approach the Treasury, and not me, upon such a subject. What I have to do with lighthouses and lightships, and the only fund I can dispose of, as you are aware, is the Mercantile Marine Fund. Now, one of the speakers has already alluded to the experiment which has been made in this matter with regard to the Sunk Lightship. I think a cable was established between the Sunk Lightship and the mainland for something like four years, and the result of that was that a Committee, composed of Lord Crawford, Sir Edward Birkbeck, Sir George Nares, Mr. Trevor, Mr. Sydney Webb, Sir Thomas Sutherland, Captain Hozier, and Mr. Alfred Holt, reported that although the experiment had shown that electrical communication could be established even in such positions, yet that the experiment should be discontinued as really having been of no service. I should say that Sir Edward Birkbeck dissented from the discontinuance of the experiment, but in his reservation he thought that a more extended trial should be made for the further period of not less than five years, and that the cost should be met by direct vote from Parliament. All the other members of the committee reported that the experiment should be discontinued, and Sir Edward Birkbeck joined with them in declining to advise that electrical communication should be established with outlying lighthouses and islands, with the special purpose of saving life at sea. Now that is the position of the case at present. You wish that the experiment should not only be taken up again, but that it should be very largely extended, and, in fact, my recollection of the short discussion of the subject at the meeting of the Chamber of Commerce is this: That there was a desire that electrical communication should be applied to practically all lighthouses and lightships. I felt that that was impossible, and I asked you for a list which you have been good enough to give me. I should like, I confess, to have some further evidence that those whose contributions form this Mercantile Marine Fund desire that this work should be done. Colonel Hill, and all of you, are aware, of course, that it comes from the Light Dues which are paid by the shipping interest. Now, you represent, no doubt, to some extent the shipping interest, but not to such an extent as other organisations which exist; and I call your attention to the fact that two gentlemen, Sir Thomas Sutherland and Mr. Alfred Holt, who certainly are very representative men in the shipping interest, reported that in their opinion the Sunk experiment should be discontinued and no further experiments of the kind should be made. The request you have made to me to-day that this should be done, to some extent in certain places, at the cost of the Mercantile Marine Fund, would, I think, come to me more strongly if it were backed by those who pay. I do not know whether Colonel Hill could undertake to answer to-day for the Chamber of Shipping, but perhaps he might have the matter brought before them.

Colonel Hill said that he thought the shipping interest would probably not be averse to making some contribution.

Sir Michael Hicks-Beach: I am not asking for a moment that the Light Dues should be increased in order to bear the cost of this experiment, because, as I say, you do not ask me to-day for a very large expenditure. You merely ask, as I understand, that electrical communication should in certain places be established and that the matter should be further tried.

Colonel Hill said that there was a very strong feeling that this was a matter of such great national importance that they might fairly ask the Treasury to undertake it.

Sir Michael Hicks-Beach: Then I must ask you to go to the Chancellor of the Exchequer and persuade him to give you a grant for that purpose. But I am perfectly confident what his answer would be to me if I were to make such a proposal to him. All that I have to deal with in the matter is the Mercantile Marine Fund.

Colonel Hill said that, knowing that several departments were involved, they thought it desirable to go to the Prime Minister, who represented them all, and they now came to Sir Michael, at his suggestion. He hoped that if they succeeded in convincing him, possibly he would communicate with the other branches of the Government.

Sir Michael Hicks-Beach: I tell you frankly that I am disposed, seeing the strong feeling that there is among many persons very much interested in this matter, to pursue the experiment somewhat further. I do not think it is enough to take the experiment on the Sunk Lightship as definitely concluding any action in the matter, and I should be perfectly willing if the shipping interest were willing that, at any rate in some of those places (of course they would have to be considered by my department, and by the lighthouse authorities), or in some other places, measures should be taken for establishing communication even at the expense of the Mercantile Marine Fund. I do not think that I can say anything further that will show you more conclusively that I am in sympathy with you as far as I can safely go. But I should be very glad if your request to me to-day to make these experiments in certain places were backed up by the Chambers of Shipping.

The deputation then withdrew.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

MONDAY, June 22nd.

London Chamber of Commerce.

3 p.m. Meeting of the Committee of the Electrical Trades Section at Botolph House.

THURSDAY, June 25th.

Chemical Society.

8 p.m. Extraordinary General Meeting.

FRIDAY, June 26th.

Physical Society of London.

5 p.m. Ordinary Meeting. Papers to be read: (1) "The Construction of Non-Inductive Resistances." By Prof. W. E. Ayrton and T. Mather. (2) "The Influence of Surface-Loading on the Flexure of Beams." By C. A. Carus-Wilson. (3) "On Pocket Electrometers." By C. V. Boys. (4) "On Electrification due to the Contact of Gases with Liquids." By J. Enright.

Royal Institution.

9 p.m. Faraday Commemoration Lecture. By Prof. Dewar F.R.S

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

A New Combustible.—A successful experiment was recently carried out at Rome with a new combustible. It is a preparation of lignite, of which there are very rich deposits in Italy. A train was run from Rome to Frascati, and ran easily up one of the steepest gradients of Italy. The quantity of fuel used during the transit was 367 kilogrammes, as against 300 of ordinary coal. The train was a heavy one of eight carriages and luggage van, and there were 70 passengers. The smoke from the new combustible is very light, and not disagreeable in odour.

For Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements should be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday.*

SMALL PREPAID ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The Directory was established in 1883, and the 1891 Edition, published on the 23rd February, 1891, consists of 900 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with well-written Biographical Notices of leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1891 should be ordered at once. Price 5s., post free 5s. 9d. Abroad postage extra. Prospectuses free.

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

"THE ELECTRICIAN" *Series at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING. Vol. I. Price 7s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Vol. I. Price 6s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

Several Further Volumes in Active Preparation.

THE FARADAY CENTENARY.

It is rather discomposing to have to associate the idea of centenary with the name of FARADAY. He and his achievements belong so intensely to our own day that it is a shock to begin to memorialise him as belonging to the past. It may be held better in general to commemorate the maturity and the climax of a man's life rather than his birth, which at the time of its occurrence is usually a particularly obscure event. The year 1687 is the date to be commemorated in connexion with NEWTON, the date of the appearance of the Principia. If the date of the discovery of magneto-electricity is sufficiently definite that probably would be regarded as the climax of FARADAY'S life.

Many potentially great men, probably, are born, but the hardship of circumstances is too severe for most of them, and we only discover or get the benefit of a few. Nature is proverbially wasteful, and not more of genius than of anything else is she likely to be specially economical if we leave her alone. But it behoves us to regulate and modify nature, in this as in so many other respects, and in process of time so to ameliorate the common lot as to give every human being a chance of developing what good and great things there are in him. It has, we fear, to be admitted that the interference of man with nature in this particular direction, at least since the rise of great towns, has not even tended in any beneficent direction, but rather the contrary. Recently, however, the direction of effort has been more encouraging—more enlightened; and in the matter of primary education, at least, we may hope before long to be able to hold our heads up once more among the nations,

Digitized by Google

instead of patiently admitting inferiority. For secondary education at the present time very little good can be said. It, too, must before long be taken in hand, and the terrific waste of life and opportunity, consequent on the incompetent system of teaching and the scientific ignorance of the class from which secondary teachers are drawn, must be checked. In higher education we are all right, or, at least, if we err it is in a totally different direction. It suffers from no lack of competent teachers. We retain the highest men we have got for the purpose, and keep them at it for most of their lives; not hesitating to provide the President of the Royal Society with a permanent class of raw juniors who need instruction in elementary matter they might just as well and should have learnt at school, if only secondary schools and schoolmasters were what they ought to be. We get our great men and we waste them. NEWTON we put to look after our coin! It was doubtless the most valuable thing we had about us, and hence it was quite appropriate to utilise the greatest scientific man of all the ages as master of our beloved Mint. But it is a perennial sarcasm.

The career of such a man as FARADAY teaches many things, among others these two:— 1. Take care of your obscure children, and never despise a human being, unless he has shown himself despicable after he has had a fair chance. 2. When a man has come to the top and shown that he is of sound judgment, strong character, bright genius, and steady industry, do not waste these qualities by employing him in trivial or frivolous pursuits. He may teach a little, but don't waste all his life in teaching, especially not in teaching up to a standard suitable to a school. Above all things don't use him to make money, either for himself or for other people. Money may be the test of success in business; it is no test of success in science. A livelihood a man must earn; but the less of his energies that go that way, the better. FARADAY, with splendid wisdom, took his life into his own hands, and did not drift, as it is so easy to do. He decided that his life should be simple and his wants few, that he might have the more time for his chosen pursuit. The rest the founders of the Royal Institution did for him. "Here," they said practically, "is a place where you need not teach, where your laboratory will not be incommoded with students, but where you may work in peace. We will provide you with some rather dingy and small rooms, we will give you apparatus in moderation, and will pay an assistant, whom you must teach to be competent. If you are satisfied with a modest salary, here you may spend your life, devoting it entirely to original investigation; except occasionally, when you will be expected to come out of your shell and tell us about what you have been doing. We shall come, some of us, only to have a quiet snooze after dinner, or to see some pretty experiments; but the experiments after all are part of nature, they please you as much as, or more than, they please us, and you won't mind showing them. Moreover, we can tell you this, that if only you have got something good to say and know how to say it intelligibly, all the best men of the country and many of other countries, will come to hear you, and your audience will not be limited to fashionable ladies and gentlemen, though these will be by no means excluded." The Royal Institution has done more for British science than it knows. It has provided a home for a succession of distinguished men whose names are, or soon will be, household words; it has also set an example which will one day be followed, either by private endowment or by State aid, and other homes of research will spring up among us, as we now find budding, here and there, a few centres of higher education.

Of FARADAY'S work, Lord RAYLEIGH and Prof. DEWAR remind us in this and the following weeks; and it is well to recall the chemical side of his work as well as the more purely physical. The liquefaction of gases, a process which has now advanced a long way towards pe fection, we owe to him, as well as the effect of magnetism on light and the production of electricity from magnetism. But, after all, it is the life more than the work that has the greatest charm for us. Other men can work; not every man can worthily live. And when a man of genius lives a clear, calm, contemplative, serene, and dignified existence in the midst of this bustle and feverish activity, in the world and not of it, he conveys a lesson, quite unintentionally, to all future generations of his race, which may well stimulate ingenuous youth to aim higher and to live more simply. His life constitutes a service to his country and to mankind, the memory of which the world will not willingly let die.

TELEGRAPHIC COMMUNICATION WITH LIGHTHOUSES.

The result of the deputation which was received by the President of the Board of Trade, on Friday last, on the subject of telegraphic communication with our lighthouses, if result it can be called, was fairly satisfactory. A deputation to a Government department rarely expects to receive a definite assurance that its prayer will be granted, but, on the other hand, it seldom meets with an unqualified rejection. One of the reasons why it is so difficult to "get something done" in this case is, that it is by no means an easy task to discover the right department to approach. The memorial, which we print in another column, "showeth, that, inasmuch as a sacrifice of life and property takes place . . . it is desirable that a system of telegraphic or telephonic communication be established between coastguard and lifeboat stations, lighthouses and lightships, . . . and the general telegraphic system." No Government Minister of Public Safety is appointed to act in conjunction with the "sweet little cherub that sits up aloft," and we must be content to watch that the broad principle of humanity, which cannot be said to pertain to any one department, is endangered by none. But as the petitioners pointed out that property was sacrificed as well as life, Sir MICHAEL HICKS-BEACH was not slow to refer them to LLOYDS, who take care of trade matters. When coastguards were referred to he had to direct them to the Admiralty; when lighthouses were alluded to they were reminded that the keepers "have pretty well enough to do in the ordinary way to look after the lights," and when telegraphic service was mentioned, Sir M. HICKS-BEACH was of opinion that the cost of it ought to be borne by the Treasury, and therefore, said he to the deputation, "you should approach the Treasury, and not me, upon such a subject."

Consisting as it did of practical men, the deputation, had foreseen that several departments were involved, and, recognising the difficulty of divided responsibility, had taken the sensible course of approaching Lord SALISBURY. He recommended them to go to the President of the Board of Trade, and this recommendation, while not saddling the latter with any moral obligation or bounden duty, drew from him a most satisfactory expression of sympathy. He admitted that the single experiment on the Sunk Lightship was not definitely conclusive, and volunteered the information that the only fund of which he could dispose was the Mercantile Marine Fund, which relies on the light-dues paid by the shipping interest. While it is true that the matter is one which closely concerns the shipping interest, it has a far wider importance, both from a humane and from a national point of view. The well meant, but partially efficient, Plimsoll rules,

Digitized by Google

and the other requirements of the Board of Trade, are examples of State interference to which the most ardent individualist will not object. Such opposition as the rules met with, useful as it may have been in preventing fussy fads, was inspired by no high motives, and there are many men who would rather increase their insurance premiums than swell the Mercantile Marine Fund by larger contributions. But where life is lost, property, too, is generally forfeited, and while the former consideration has claims on the State, the latter concerns the proprietors, from whom some contribution towards the expenses may therefore be justly demanded. But the national aspect of the matter is twofold, the apparently incompatible objects aimed at being, as we have observed on a former occasion, the saving of life by telegraphic connection between lighthouses and lifeboats, and the early destruction of life by affording timely information to our naval commanders. The Treasury has only to give the word, and the Post Office, who have long ago made the necessary estimates, would rapidly complete the work, or at least connect up a dozen or so of the more important points.

ELECTRIC AND MAGNETIC THEORIES.

BY JOHN T. SPRAGUE.

Before replying to Prof. Silvanus Thompson I must have a word with Mr. Oliver Heaviside. He has more than once suggested to me a "receptive spirit" in the study of these hypotheses; and on p. 95, in remarks evidently meant for me, speaks of the "obstruction evidenced by a carping and unreceptive spirit." Will he explain why we should manifest this "receptive" spirit? Why are we called upon to do like the children, "open our mouths and shut our eyes" and swallow what anyone offers us? I have always understood that the true scientific spirit of investigation, where hypotheses are the subject, is one of candid scepticism; that the law is—prove all things, hold fast that which is true or proved.

§ 1. I hold a theory developed from the whole work of the past the labours of all our great electricians, it agrees with every fact of nature, explains every fact in accordance with the principles of all the related branches of science. I find a new theory proposed, which overturns all our past work, which leaves experimental facts to base itself upon mere hypotheses about the properties of a substance whose very existence is unprovable; I ask for facts and am given mathematical symbols; at the utmost I am offered the assertion that Hertz has proved anything needed, though I can see nothing in what he has done which is not clearly intelligible quite apart from these hypotheses. To slightly change Mr. Heaviside's own words, § 65, "when I, as a critical thinker, look through these investigations and hypotheses, I see that they are purely artificial elaborations, devoid of physical significance, groping after mares' nests, in fact." Why bring a receptive spirit, then? I believe them to be thoroughly mischievous inventions, opposed to all true science, and I will do my best to oppose them, in the interests of genuine inductive science.

§ 2. Prof. Thompson begins (§2, p. 44) by asking me whether I have "evidence of any case in which there is transfer of energy that cannot be accounted for by the hypothesis of a lateral transfer through the medium." Of course he means electric energy; as our general experience of transfer of energy requires a material agent, I consider that we ought logically to require evidence that such a transfer ever occurs apart from such an agent. He must not call on me to find evidence; but I am ready to answer him. I have no evidence of any single case of transfer of energy as a flux through the medium at all. He has altogether omitted the real question at issue. He has dealt (in the way of evidence) solely with the phenomena of the variable periods. The real point in debate is how energy is transferred by an electric *current*. I ask him, has he *any evidence* of a single case of lateral transfer during the existence of true current? It is notorious that there is no scrap of evidence. Therefore he avoids this difficulty by a logical dodge. He says, practically, if I can show that there are *some* cases in which we must agree that energy is transferred through the medium, I am entitled to assert that it is so in all cases. Bad logic and worse science. He omits the fundamental circumstance that the conditions are entirely different. Where energy is transferred, we find only a temporary action, clearly of the nature of a static stress, which only transmits the energy needed to establish the stress, and returns it when the stress-producing conditions cease to exist. He has, therefore, no title whatever to claim, without evidence—and against actual evidence—that transfer of energy can be effected by the medium when the conditions are those of a continuous flux instead of a static stress, and the energy is not returned.

§ 3. More especially has he no title to claim for his hypothesis any superiority over the older theory, which recognises the essential difference of the two conditions, and clearly explains both. But the only experimental evidence which Prof. Thompson offers is to demonstrate certain well-known facts, which any theory must take into account, and which I fully treated in my articles. I am disappointed. It is a pleasure to read Prof. Thompson's writings when dealing with real things. Then he moves steadfastly, and makes all thing clear; but it is very different when he is attempting to give substance to shadows, and convert make-believe hypotheses into science. He must excuse me if I pull his argument to pieces.

§ 4. In the first place he has taken up the proverbially dangerous position of sitting upon two stools. He poses as the champion of one definite assertion, viz., that the energy of the source goes direct from the source, *viâ* the medium; that the conductor—the circuit plays no part in *transmission* of energy, but only receives it *from the medium*, acting as a waste pipe to serve some inscrutable purpose.

§ 5. But the only thing which he proves, and bases his subsequent argument upon, is that energy is transmitted *from the conductor*, not from the source; (when he shows it going from the source, he does not prove, he only exercises his fancy). I warned him beforehand that his Proposition V. involved this consequence; in it he speaks of "transfer of energy through the medium *from the primary circuit* to the secondary." But the very basis of his proper argument is that the energy does not go from the source into the circuit at all, but from the source direct to its work.

He has taken great pains in his figures, 1—5, to prove my case, and contradict his own doctrines. Let us first study those figures and his reasoning. Fig. 1, p. 44, shows a source connected to primary coil A, and a similar parallel coil B connected to a galvanometer G. It is really identical in principle, though altered in form, with my Fig. 8. As it happens it will enable me to demolish Prof. Thompson's argument better than my own does. For just consider: What is the process of transmission? Prof. Thompson, leaning on one of his stools, kicks over the other, the passage of energy from the source: he adopts my own view, that it travels, first *viâ* the wire to A, then "in some way" from A to B, and then *viâ* B to G. Now, what is the *modus*—the some way? No one knows better than he, and yet Prof. Thompson ignores the simple truth, that it is by the setting up of magnetic lines of force, which thread both his coils, and that, therefore, the energy, dependent upon the ampere-turns of A, must come from A and *not* from the source direct.

§ 6. I say he ignores the magnetic *modus*, and I will prove this by his Fig. 5 (p. 65), where he shows the two coils connected in series, and gives us arguments valid only if we ignore the fact that it is by magnetism set up in the medium, and not by any direct transfer of energy from wire to wire, still less from source to wire, that the phenomena are produced. Just let me knock the bottom out of the tambourine on which he plays his pœan in G. In Fig. 1, with the coils insulated, A generates magnetic lines, which, traversing B, set up a stress and momentary current in its wire manifested as work in G. I explained all this on the other theory in my §§ 66—69. In Fig. 4 he shows the current produced

Digitized by Google

in both A and B, connected in series as one, and triumphs in the excess spark, etc. Of course he has doubled his magnetism; in Fig 5 he opposes the coils in series, and again triumphs. Well, he has simply neutralised the magnetism, and therefore diminished the storage of energy. I do not wonder that he sees that these phenomena are "compatible with the notion of propagation of current by longitudinal forces." True he says, "*if taken by themselves.*" I am content to take them any way, but I seek in vain for any evidence that they are compatible with, or explainable by, the notion of lateral or other transfer *from the source.* At all events Prof. Thompson does not even pretend to give it.

§ 7. It is the same with Figs. 2 and 3, both show transfer *via* the circuit; the only "medium" taking part in it is the space between the two agents, the inducing and induced circuits. The only evidence really given is that of energy traversing the conductors, at the spark space B, in Fig. 2; and in the copper plate B, in Fig. 3. No one doubts that energy has passed by a stress in the medium. But how does it reach the "medium," that is the space between A and B? Prof. Thompson *shows* it as passing from A, to which conductors convey it from the source, as I say; but he *says* it reaches B from the source (at least that is the only meaning I can attach to the theory) and is altogether silent as to the functions of A, or how the energy is first got to A.

§ 8. He is worse than silent, for (of course, unintentionally) he misrepresents my position on this subject. He says, § 14, p. 105: "To ask how the energy knows where it is wanted is trifling with the question." He also compares my question to an imaginary absurdity of his own device.

I submit that my question is *the* question, the point on which the whole theory turns. Prof. Thompson says energy goes direct from the source; he and all his side say that this energy is propagated in the same manner as light is; that electricity and light are identical in essence, varying only in length of wave or something of that sort. Well, light is radiant, and has no special directive power. It is not trifling to demand from these hypothesisers an explanation (it only needs to invent a new property of the ether) of what agency controls the direction. I know what it really is; it is the circuit, the conductor. But those who deny this must substitute something else. The search for a "waste pipe" will not do, because while there may be 1,000 equally suitable dispersers attainable, the energy will select the one which completes the circuit, and that only, except during the variable period, when it exerts a special but still localised action.

§ 9. But Prof. Thompson also misrepresents facts when dealing with what he calls "a most misleading statement" of mine, viz., that electric energy is linear and controlled, while light is radiant and uncontrolled *except by an outer agency.* Now, these words in italics involve the whole argument, and show us something which cannot be evaded. Prof. Thompson and his friends must show us what it is which guides the energy, and transforms it from radiating lines into locally directed lines. My question is not a ridiculous one, as he pretends, but an imperative one. Why does the energy go to the *wire*, as the hypothesisers assert? The circuit wire conducts nothing, not even an impulse: why does this radiant energy seek that wire and follow it 1,000 miles away through any amount of twistings? Very like the transmission of light that, is it not?

§ 10. Now, as to trifling with the question, I must really ask Prof. Thompson to say if he does not do this in his § 2. Is it really scientific argument to talk about what might have been our perceptions or conceptions if our existence had been conditioned by an ocean of quicksilver instead of air? If it be the fact (I have suspected it for some time) that these new theories are really applicable only to an altogether suppositious universe, say, of *n* dimensions, in which all our familiar truths are converted into unrealities, and actual nonsense becomes solid truth, I should respectfully make use of the waste basket. Life is too short and too full of serious realities to waste time over journeys with "Alice in Wonderland" in search of truth. We do live in an atmosphere of air, and surrounded by dielectric matter, and not by a conductor. That, then, is the condition upon which we ought to base our conceptions; if the difficulties of the new theory are, as we are now told, the natural inevitable result of this environment of thought (and air), I suppose we must wait to clear them up until we find ourselves in the more favourable state of living in a bath of quicksilver. Possibly the new theories may be true in mercury, but we want them proved here, and I do not see that we have yet moved a single step towards that result.

§ 11. Let us go back to Figs. 1 to 5. In Fig. 1 the two coils are placed parallel to each other; let B be turned, so that it is at right angles to A. No effect would be produced. Why not, if it is a mere question of collecting energy in a radiant state, whether from A or from the source? The wire would equally present equal and similar surface to the rays, and be equally fitted to serve as that "sink" or waste pipe. But the magnetic lines would not traverse the space in B, and could not develop the current which is measured by G. But now replace the air core common to A and B by an iron core; it makes no difference whether the coils are parallel or at right angles, *i.e.*, whether the core is straight or curved: the magnetic lines traverse both coils, and now G will testify to the momentary current alike in both positions.

In Fig. 3 we are furnished with the proof (positive, not merely negative) that the constant current does not transmit energy, which guessers might say it does, only our apparatus does not show it. Heat is developed in B by an alternating current in A, because of the successive momentary currents set up in the copper plate B. A steady current in A produces no heat in B, because there is no current in B; but now move B about while that current exists, and we have heat and mechanical resistance; the last due to disturbance of the lines of force, not of energy, and the consequent motion of the molecules of A while rearranging themselves in the lines of force; the energy does not come *via* A, but is mechanically applied to B in the effort to move it among the lines of force. In Fig. 4 we have the two coils connected in series, generating double magnetism in their one air core, and therefore double reactions of energy. In Fig. 5 we have them arranged to produce opposite currents, and therefore a magnet with consequent poles, absorbing only half the energy and giving up very little, because the magnetism will react in the core itself instead of externally.

§ 12. Let us now examine the attempt to deal with the case of constant current, p. 103, Figs. 6—11. I have two objections to make: 1. The figures and the argument are wholly imaginary; no scrap of evidence is given, or can be given, that they correspond to any natural facts. 2. They do not cover the whole facts, and they misrepresent the facts, so far as these can be known and tested. I must ask my readers to closely follow my analysis of Prof. Thompson's argument. He says there is nothing in the way of proof "that energy is transmitted by an end thrust along the wire of the circuit." But there is this evidence, that in the wire we know something is going on; that which we call current—but the nature or direction of which matters nothing to this argument; be it what it may, *it is there;* the energy does actually *issue from the wire as heat;* we know that; it is a mere guess that it first enters the wire without evidencing its presence in the space it is asserted to traverse.

Now, consider Figs. 8 and 9, or, as it is the prettiest and most imaginative, let us take 8; are we to be told that those dotted curves represent, in the smallest degree, the known facts; is it not known that whatever occurs in the enclosed space occurs equally outside that space; that if energy crosses from source to circuit by those paths, similar paths surround the whole wire? Instead of a nice circle, clear of obstructions, let that wire go about in all sorts of fashions, as real circuits do —the symmetry, the apparent reasonableness, of those dotted lines vanishes at once.

13. Now I come to the question which is said to trifle with the subject. What guides these lines of energy into all sorts of convolutions, and links their paths from the source to the wire? *It is the question;* and, moreover, the new theory gives no answer. If the energy leaves the zinc surface, and becomes radiant, exactly as light is, what gives to it a definite direction, independent of straight lines, which light unquestionably does

Digitized by Google

not possess? No electrical theory is of any service which does not include this dual action with unity of nature. In the wire theory we have this, the action starts in the wire in both directions; that was proved long ago by Wheatstone's spark experiment; it is proved by the certain fact that a complete closed circuit must be provided to permit true current to be maintained. Why should it be necessary on the sink theory? Cut the circle of Fig. 8 at each figure. Why should not space 5—6 serve as sink to source, 5—6 irrespective of the others, if it is really true that the energy goes as shown?

In what way does Fig. 8 explain the phenomena of so-called "potential," if each cell does act independently in the manner said to be "rational" in §12? In what manner does the theory explain the relations of energy to the dynamic, magnetic, and chemical actions of what we call current? I invite the other side to take my Fig. 5 and explain, on their theory, the several actions and dissipations of energy, which I have clearly and simply explained on the conductor theory. They cannot do it; at all events no one has ever yet done it. Prof. Thompson says, §11, "any theory which merely takes into account the flow of current, and neglects the distribution of electric potential, is obviously incompetent to deal with the question how the energy is propagated." Does he mean to imply that the old theories do this? Can he mean, in face of my Fig. 5, that I have not taken this into account? How does he do so in Figs. 8 and 9; do they show any reason why his cells in series give a higher potential, when he actually makes them deliver their energy (which is potential) in parallel, to what are practically separate sinks? In return, I say no theory is of any value which waives these fundamental facts:—

1. A closed conductive circuit, which is essential.
2. A medium which takes up stresses only, *i.e.*, a dielectric.
3. An action related to the equivalence and structure of matter.
4. The functions of energy, mechanical and chemical, in the circuit.
5. The functions of energy in the dielectric.
6. The "danger of attempting to extend hypothesis beyond the limits of actual observation" (your Editorial, p. 73).

§14. Now contrast Figs. 8 and 9. Wherein lies the difference of direction of the energy lines? Simply in the difference of conductance in the wire circuit. Again I ask—how does the energy, radiating (like light) from the zinc surfaces, know where to direct its path, which light never does? "flowing outwards into space and swirling round." Now, will Prof. Thompson illustrate this? Will he show us any instance of a motion once set up, swirling round, except under some new force? That is what I want defined. Why does it swirl? What swirls it? It moves contentedly enough in my wires. The equipotential paths and parallels do not explain, because the energy itself creates them.

Then there is this curious fact: it goes mostly where there is least conductance, there being the same current everywhere. We are told, p. 13, "just enough going to any given part to keep up the radiation of heat from that part." As a fact to be explained, yes: but why? the energy produces the heat. The energy wants a waste pipe, and curiously enough goes mostly to the worst waste pipe, where there is least material to dissipate it. Certain assertions are made at end of §14, true enough as facts, but not as explanation, because they do not distinguish cause and effect. We have radiant energy from zinc to wire, across medium; radiant energy as heat from wire back into medium; electric potential, set up by energy at the zinc, of course, and variable equipotential lines due to resistance in the wire, which wire is only a sink, all in a lump; sometimes cause, sometimes effect, just as you please. Still worse, we have it proved that the electric potential increases as taken through the cells, proving an action of energy in the linear circuit, and then this fact absolutely dismissed, except in the vague term potential, and the separate cell action invented.

§15. Prof. Thompson says that the non-relation of energy to current and its relation to the non-conductance, *i.e.*, resistance of the circuit, is "itself a ground for thinking that the path of the current is not the same as the path of the energy." But this is exactly what happens in mechanics, in all cases of friction. I defy any one to give any intelligible reason why in Fig. 9 the energy should nearly all go to the thin line, as shown, or explain the sympathy between energy radiant at the zinc, and needed (for no particular purpose except to transmit a current, itself of no particular use) at parts of the wire. The conductor theory is simple; the current which originates at the source means a molecular motion. Where the wire is thinnest those motions must be most rapid; rapid motion, greater friction, consumes more energy in waste heat, and the energy transmitted pays toll as it goes, just as a caravan does when passing through different territories.

I now invite Prof. Thompson to make his Fig. 9 into a fact, and show us the passage of energy; it is easily done, if the thing exists; let him place a glass pan, containing bisulphide of carbon, or other suitable liquid, and prove by polarised light the existence of these lines of stresses corresponding to the alleged energy streams. I suppose he knows as well as I do that he will not get them, as he ought to do, but will get evidence of the cross stresses of magnetism instead, if the current is strong enough; at all events, he will get nothing at all resembling his imaginary lines.

§16. No test will manifest any action within that space, except the lines of static stress between any two points, such as that shown a, a', Fig. 9; but these have no relation whatever to transfer of energy direct from the source; and what they prove is that energy is present at every part of the circuit, within it, and ready for an outlet. This also has nothing to do with the enclosed space, for the electrometer may be 1,000 miles away, and will act just the same as if in the middle of the space, proving, beyond dispute, that the energy has travelled from the wire circuit, and that the conductors carry energy and produce electric stress, or potential, 1,000 miles away. In fact, there is no experimental proof existing of the passage of energy, during constant current, across the medium, the real point in debate, while every use made of electric currents is practical evidence of transmission of energy by the circuit.

(*To be continued.*)

PROF. PERRY'S ELECTRIC SUPPLY METER.

Those who peruse the list of new patents have been made aware that Prof. Perry has for some time been engaged in the construction of a new meter, and our French contemporaries have illustrated and described the instrument, from patent specifications, as though it had been *un fait accompli*. The meter, in a practical form, and with nearly all the latest improvements, was shown for the first time at the soirée of the Royal Society on Wednesday last. Prof. Perry informs us that he has always been of opinion that, although any man with a knowledge of electricity and mechanism could invent an instrument to integrate current or energy, it was impossible, by going outside the two principles enumerated by Prof. Ayrton or himself in 1883, to obtain a simple, that is, a cheap, lasting, and accurate supply-meter. These two principles were—(1) let electro-magnetic forces quicken or slow the time of a clock, and (2) use an electro-motor, and let its motion be retarded by forces proportional to the velocity. Such forces are fluid friction when the motion is very slow, and resistance due to Foucault or eddy currents.

The present meter works on the second principle, but it has to be observed that the conditions are not simple. First, if there is more than the merest trace of ordinary solid friction in the motor, as this alters with time and other circumstances, even if balanced by a constant current torque, it destroys the accuracy of the motor. Hence the pivoting must be excellent, and all solid friction of brushes or rubbing contacts must be avoided.

Second. If mercury cups are used as brushes, two errors are introduced. The nature of the contact alters rapidly with time, the mercury getting oxidised and dirty. If anything dips into mercury there is a friction between it and the mercury at the surface which is really of the nature of a solid friction and not a fluid friction.

Digitized by Google

Again, it seems impossible to do away altogether with ordinary fluid friction. Now, at slow speeds, fluid friction follows a law which is just what is wanted, but this is not the case at high speeds. Again, it alters considerably with temperature and other conditions.

There are experimenters who have wasted thousands of pounds because they have assumed that fluid friction is proportional to the square of the speed. Now, this is the case only at high speeds, and a meter runs at all sorts of speeds. The highest speed of this meter is one revolution per second, and this is when 100 amperes are passing through it, and even at this highest speed the fluid friction follows a law not very different from proportionality to speed. When these instruments are being manufactured by well-devised and accurate machinery their very highest speed will be a crawl.

The meter exhibited is the outcome of much thought and experiment. The solid, or *quasi* solid, friction is very small; the fluid friction is still much greater than is desired, but it

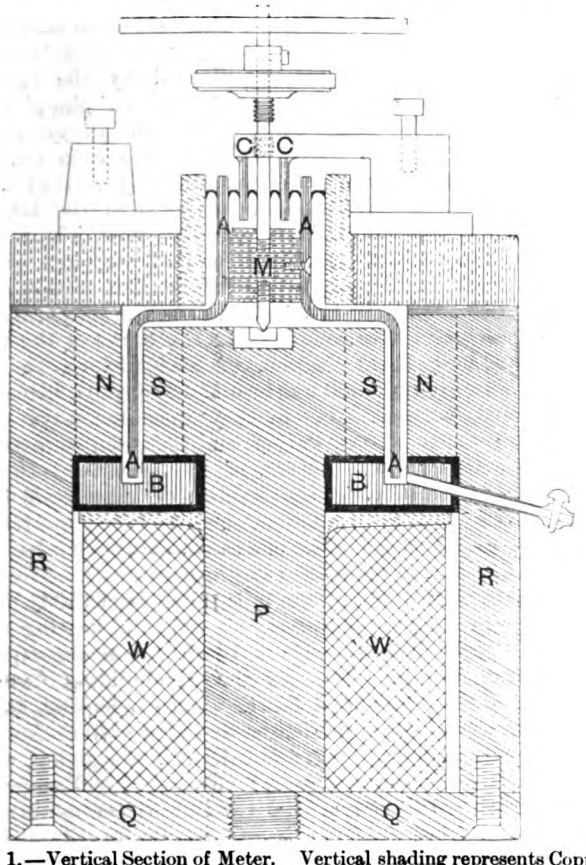

Fig. 1.—Vertical Section of Meter. Vertical shading represents Copper, diagonal shading, Iron; the space filled with Mercury is left white, the upper surface being shown by the rounded outlines.

follows a law which is nearly right, as the speeds are small, and, besides, *all other resistance is completely masked* by an enormous Foucault current resistance. It required a considerable amount of calculation and experiment to determine just the best method of making this resistance as great as possible.

The field of the motor being F, and the current through the armature C, the turning moment is proportional to F C. The resisting moment is a small, nearly constant term a, due to solid friction; a term $b\,n$, due to fluid friction, in which n is the number of revolutions per second (b cannot be relied upon to keep quite constant, except at very small speeds), and a very important term $c\,F^2\,n$, representing the Foucault current friction, on which great reliance may be placed. We have then—

$$F\,C = a + b\,n + c\,F^2\,n,$$

or,

$$C = \frac{a}{F} + \frac{b}{F}\,n + c\,F\,n.$$

It is, therefore, obvious that by making F as great as possible the terms $\frac{a}{F}$ and $\frac{b}{F}\,n$ become less important in comparison with $c\,F\,n$.

That this result had been attained was evidenced by the great slowing of speed of the meter for a given current when the field was increased. In use, the field magnet is sufficiently saturated to make an alteration of a few volts at the field-magnet terminals of very little effect.

Fig. 1 is a section. A is the armature; it is a cylindric copper vessel, closed at its upper end, except for a few holes. It is like an inverted claret glass, and is immersed in mercury, in which it revolves. It receives current from a heavy ring, B, of copper, the current passing through the mercury to the lower edge of A. It passes in a cylindric current sheet upwards through A, and passes from A through the mercury to C, a fixed tube dipping into the mercury. At this upper part there is a quasi-solid friction, but it is very small. The armature is coated with insulating varnish everywhere, except at the places where it receives and gives out current, and at these places it is nickel plated; hence, in the field there is no current whatever through the mercury. A phosphor bronze spindle gives motion to the counting arrangement. The spindle is in two pieces, so that the upper part may be insulated. It can be fixed rigidly to the fixed bracket when being carried about. M is ebonite. S P Q R N is a cylindric or tubular magnet wound with fine wire, W. The cylindric poles, S N, form the two sides of the trough in which the armature revolves, and 7 or 8 watts are expended in maintaining between them an intense magnetic field. But this field is not uniform. The plan of the pole pieces, Fig. 2, shows a number of wooden plugs, between which iron poles project, so that every portion of the cylindric part of the armature passes from intense field to almost no field 10 times in every revolution, and the result is that the Foucault current friction is about 25 times the fluid friction

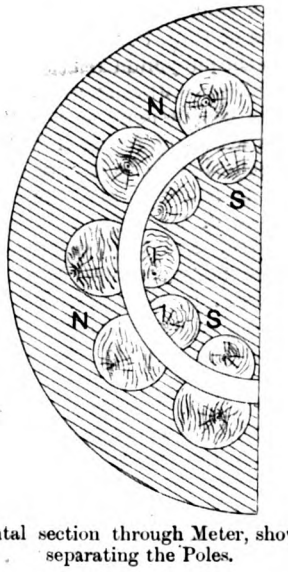

Fig. 2.—Half horizontal section through Meter, showing Wooden Plugs separating the Poles.

In such an instrument, the smaller the clearance thicknesses inside and outside A, the more exact will the intrument be in its record. It can be shown that the best results are obtained when the thickness of the copper is equal to the two clearances. Until the meter is manufactured in considerable numbers the clearance will be much greater than it ought to be. In the instrument exhibited the copper was much too thin and the clearance much too great, and yet:—

1. It started with 0·2 ampere. This represented the error due to solid friction.

2. From 2 amperes to 100 amperes there was only one place (namely, at 10 amperes) where the error was so great as 1 per cent.

3. There was nothing to alter with time.

4. Temperature errors balanced themselves.

In the patent list in *The Electrician*, Vol. X., p. 730, of December 23, 1882, is illustrated the meter of Faure, in which a copper bell dips into mercury. This is the earliest meter which depended for its action on the rotation of mercury, or

Digitized by Google

of a conductor suspended in it. In a patent of Edison, in 1883, the identical arrangement is to be found. The development of this idea most familiar to our readers is the Ferranti meter. Here a quantity of mercury is set in rotation, and this motion is imparted to the recording train by vanes which take up its motion, as do the ebonite vanes in the Siemens water meter. Foucault currents are absent from the Ferranti meter. Again, the uniformly distributed, but varying magnetic field of the Ferranti meter, depends on a series winding through which the main current flows, and the friction is balanced by a shunt winding. In Prof. Perry's meter, on the other hand, the field is maintained by a shunt coil, it is not uniformly distributed, and is practically constant in strength.

The working and the theoretical accuracy of the Perry meter is the outcome of the practical study of the phenomena of fluid friction. Ever since Stoke's classical work on the viscosity of fluids, fluid friction has been treated by many mathematicians as being simply proportional to speed. This was Stokes' discovery, and is true for small speeds. Engineers, on the other hand, starting from hydraulic experiments, and the resistance offered to vessels propelled through the sea at several miles an hour, have always assumed that fluid friction varies as the square of the velocity. The apparent discrepancy was finally settled, as it should be, by a beautifully simple experiment of Osborne Reynolds's, who showed that a submerged jet of coloured water flowing into a tank issued in a mere line at low speeds, and at a certain definite point broke up, owing to the formation of eddies. As soon as the motion thus becomes turbulent, the friction being made up of viscosity and of eddies is practically proportional to the square of the velocity. Such is the importance of accurate knowledge of mechanical forces in the construction of electrical instruments that we must give a brief account of the further investigations of Prof. Perry on the fluid friction, since they bear directly on the subject before us. The friction in this meter is practically all pure fluid friction, and, the speed being so small, it is directly proportional to the velocity. Prof. Perry has found that when a body is partly immersed in mercury the friction at the surface—that is to say, at the line of contact—between the body, the mercury, and the air is of the nature of solid friction. One of the copper bells of his meter, suspended by a fine steel wire, and partly immersed in mercury, as in the Faure meter, rotated through, say, one turn, and then left, will stand in that position for hours, since the quasi-solid friction acts at a considerable leverage; but if the surface of the mercury be raised, so that the whole bell is immersed, the friction takes place only round the spindle, and at so small a radius that it is negligible. This quasi-solid friction, we understand, appears to be independent of the length of the line of contact, just as ordinary solid friction is independent of surface, but the radius at which it acts is all-important. It is satisfactory, therefore, to know something about this quasi-solid friction, since it determines the serious matter of the starting current, and Prof. Perry is confident that the 0·2 ampere at which his meter begins to move is well outside the limit which will be attained in practice.

THE ELECTRICAL MANUFACTURE OF PHOSPHORUS.

The large and increasing demand for phosphorus, not only for its main use, viz., the manufacture of matches, but for its subsidiary applications in the organic syntheses which form one branch of modern chemical industry, and in the production of many of the phosphor-alloys that have recently come into vogue, has made the question of its economical production of much commercial importance, as well as of technical interest.

On considering the method of manufacture at present generally employed, it becomes evident that the chief cost lies less in the raw materials than in that of the plant and labour necessary for the production of phosphorus from them. The outline of the process is simple and may be told in few words. Some form of calcium phosphate—formerly bones were used, but mineral phosphates are now preferred—is treated with sulphuric acid, the liberated phosphoric acid separated from the calcium sulphate produced at the same time, by filtration, the solution of the former concentrated by evaporation, mixed with charcoal and heated strongly in small retorts. The carbon reduces the phosphorus from its oxide, and it, being volatile, distils, and is condensed in the usual way. As in the manufacture of sodium by the old process of reducing sodium carbonate with carbon, the chief objection to this method consists in the high temperature necessary to effect the reaction, and in the loss of a portion of the product (phosphorus in this case) through cracks in the retorts, the frequent renewal of which is also costly. The loss of phosphorus in this way is increased by the circumstance that the operation is conducted at a pressure slightly above that of the atmosphere, on account of the exit from the retorts being provided with a water-seal.

In a recent article we pointed out that there were many indications of a growing application of a principle which we then enunciated, namely, that of applying heat to the centre of a mass of material, the temperature of which it was necessary to raise for the purpose of effecting some chemical reaction, by means of an arc formed at the required spot, and instanced the Cowles furnace, and the process adopted by the Electrical Construction Corporation for the manufacture of phosphorus, as cases in point, at the same time indicating the advantages that accrued from such an arrangement. Since then Dr. Readman, of Edinburgh, who had independently arrived at the same idea as Messrs. Parker and Robinson, of the Electrical Construction Corporation, and who has now joined forces with them, has made public the details of his large scale experiments in a Paper read before the Scottish section of the Society of Chemical Industry, and published in its journal. His earlier experiments were conducted at the works of the Cowles Company (Limited), at Milton, in Staffordshire, the large dynamo there, giving 5,000 amperes at 50-60 volts, being available for that purpose. Before they were far advanced he became aware that Messrs. Parker and Robinson were working in the same field, and the upshot of the agreement that was come to between them, was the erection of large scale experimental works near Wolverhampton, where a site of about ten acres has been obtained on the banks of a canal, and upon it have been put up boiler and engine-houses and furnace-sheds. The power is supplied by three Babcock and Wilcox boilers of 160 H.P. each, having a grate area of 30 square feet and total heating surface of 1,619 square feet, worked at 160lb. A triple expansion torpedo-boat engine by the Yarrow Shipbuilding Company, capable of generating 1,200 I.H.P. when condensing, and 950 when worked without a condenser, and an Elwell-Parker alternating dynamo absorbing over 500 I.H.P., and giving, as may be desired, 5,000 amperes at 80 volts, or 2,500 amperes at 160 volts, when running at 300 revolutions per minute, have been set up. The dynamo is excited by an Elwell-Parker shunt wound machine, delivering 90 amperes at 250 volts when running at 800 revolutions per minute, a portion of the current being available for lighting and experimental work.

The process is quite simple, consisting merely in feeding in the raw materials, passing the current between suitable electrodes, as in the Cowles furnace, and collecting and condensing the volatilised phosphorus in the usual way. The weight of the slag amounts to about half the original raw materials, and can be tapped at the bottom of the furnace, while fresh raw materials are fed in at the top, so that the process is continuous, and, it is expected, may be run for days without intermission. No trouble from the escape of phosphorus vapour is to be apprehended, as the walls of the furnace may be as massive as is requisite, seeing that the heat is applied in the interior and has not to penetrate from without. It is claimed that the charges can be made to have as high a content of phosphorus as 15 per cent., and that the slag may be obtained with as little as 1 per cent., while as much as 86 per cent. of phosphorus actually passes into the condensers. The crude phosphorus thus obtained is of satisfactory quality, and can be purified by fusing under water, squeezing through washleather, and treating with ammonia, and afterwards with chromic acid mixture in the usual way.

The use of basic slag as a cheap phosphoric material has been tried, but without success, as the iron it contains forms a

Digitized by Google

phosphide corresponding, approximately, to the formula $Fe_2 P_3$, and containing 23-24 per cent. of phosphorus, thus leading to serious loss. Although, as already indicated, the furnaces are, with the exception of the addition of the necessary condensing arrangements, similar in construction to the Cowles, yet, on account of the need to diffuse the heat evenly throughout them, it is found advisable to limit the size considerably, those actually in use being capable of turning out about 1½cwt. of phosphorus apiece per day.

The question of the electrodes used is naturally interesting, as these subsidiary but indispensable adjuncts, sometimes prove more costly than is at first anticipated. Those made by the Cowles Company cost about 8-10 shillings each, but the Electrical Construction Corporation are using gas carbon, which is considerably cheaper.

It will thus be seen that though the work done hitherto is of the nature of an experiment, yet the experiment is on so large and well-ordered a scale that it has more nearly reached the position of a manufacturing process than many inventions introduced far more pretentiously to public notice ever do.

The key to its successful operation is, we are convinced, to be found in the adoption of the principle of applying heat in the very spot where its usefulness is greatest, doing away at one stroke with the clumsy practice of external firing at present employed in this as in many kindred industries.

It is to be noted that nothing of the nature of electrolysis takes place. The current is alternating, and the sole reason for its use is its capability of conversion into heat at any desired place. The development of this principle, and its application to manufacturing processes of the most diverse kinds, may be confidently expected at no distant date.

THE CAUSTIC SODA AND CHLORINE SYNDICATE.

Once more has the time-honoured scheme of making chlorine and caustic soda—the two commodities the production of which keeps the Leblanc process in a state of precarious vitality—been brought forward with flourish of trumpets and a florid prospectus, and has arrived at the stage of its statutory general meeting.

With the strictly financial aspect of the case we have little to do, but from an electro-chemical point of view there are some points that may interest our readers.

Until quite recently the electrolytical critic was hampered by the fact that the Syndicate was formed to take over and work an invention for which the vendor had only obtained provisional protection. The original documents being thus denied him, he had, perforce, to content himself with information of somewhat less satisfactory authenticity. The specification, however, has now been published, and a little additional information on the nature and prospects of the process can be obtained from it.

Taking in the first place, however, that which is common property, and has been put forward by the Syndicate as the justification for its existence, and studiously refraining from in any way "going behind" the statements in the prospectus, we find that, with the exception of the figures showing the oppressive profits of the Salt Union and the Chemical Union and those dealing with the purchase of the vendors' rights, the character of this document is, in chemical language, purely qualitative. It is pointed out that the new process will save two-thirds of the salt and a considerable amount of fuel and labour, that it will require smaller premises, cheaper and less complicated plant, and a shorter time than the old, advantages which are capped by another, viz., that "the entire process is simultaneous, simple, and direct, whereas by the existing methods a whole cycle of operations are required to produce the chlorine and caustic soda separately." Simultaneity, simplicity, and directness, though appealing powerfully to one's artistic instinct, are by no means necessarily of industrial value. The confusion of mind which leads to the acceptance of the fallacy that these qualities are of importance in themselves, is precisely of the same nature as that which causes the condemnation by the unthinking of a piece of mechanism as complicated when it is in reality only complex. This claim cannot, therefore, be accepted as necessarily constituting an important merit of a successful manufacturing process.

Examining the other statements quoted above, and postponing the consideration of the first, namely, that less salt is used, to be dealt with in the light of other assertions to which we shall presently refer, we may say then on *á priori* grounds it is reasonable to suppose that less labour and smaller premises may suffice, and that the plant would be simpler, but that the alleged saving of fuel is not self-evident, and that, therefore, it must be accepted with considerable reserve. These are the conclusions at which anyone well acquainted with the subject would arrive by the exercise of his own intelligence, and they, therefore, need no elaboration, and may be dismissed with the remark that an estimate, even if admittedly approximate of the economies to be effected, would be in every way preferable to loose *ex parte* statements.

Those who think as we do in this matter would naturally look for some definite account of experimental work upon which the foregoing assertions are based, and would, therefore, turn naturally to the report of Messrs. Cross and Bevan upon the process, which is incorporated in the prospectus. And here it may be well to meet an objection which is commonly made to reports of this kind, and has been to our knowledge advanced in this particular instance. Persons better acquainted with manufacturing processes than with the principles upon which they rest are often guilty of condemning an experimental investigation into, or demonstration of, a new process, on the ground that it has been conducted on a small scale. Such a contention scarcely needs serious refutation; those who are familiar both with the conduct of large-scale operations, and with the method of executing those experiments by which their success has been secured, know very well that the mode of ascertaining the best lines upon which to work, which is at once handiest, cheapest, and most instructive, consists in the device and execution of an experimental investigation, directed, not to the slavish reproduction of the conditions of manufacture, but to the elucidation of the difficult and doubtful points that have to be encountered and overcome in any considerable and novel undertaking of the kind. Premising the acceptance of this view by the majority of our readers, we may proceed with our criticism of Messrs. Cross and Bevan's report of their experiments which have been, we believe, conducted on a laboratory scale.

In the first place, that ancient delusion and snare, a working model, appears to have been used, and a kind of toy manufactory set up. The scientific interest of the process, and the originality of the invention, is apparently centred in an article known as a "Special Diaphragm." It is true that it is stated to be "perfectly efficient in separating the products of the (why "the"?) electrolysis, soda and chlorine," and to introduce a resistance which is satisfactorily low, the difference of potential between the terminals never exceeding five volts. Unfortunately nothing is said as to what proportion of the five volts is necessary for overcoming the resistance of the diaphragm, and what for effecting the work of electrolysis, or, in plainer terms, what percentage of the total available energy is consumed by passage through the diaphragm.

In the report of the statutory general meeting repeated reference is made to the merits of this diaphragm, which is said to have given rise to no trouble or difficulty, although expected, even by the patentee, to do so. The chief information tendered on that occasion was the assertion that "the principle of its construction is based on a well-known pneumatic law." Assuming the verbal accuracy of this report, the difficulty of divining from it the nature and functions of a diaphragm of this description is considerably enhanced. According to the specification, the diaphragm consists of a series of V-shaped troughs, built up one within the other, and the spaces between them packed with asbestos fibre or steatite. The *raison d'être* of this arrangement is not obvious, and its exact relation to the "well-known pneumatic law" is equally obscure. It is also difficult to see why, if asbestos be chosen on account of its fibrous character, as is apparently the case,

Digitized by Google

steatite should be mentioned as a possible substitute. If steatite, why not powdered slate, kaolin, firebrick, or some other similar material refractory to the attack of the products of electrolysis? Steatite possesses nothing in common with asbestos save its chemical composition, the physical difference between the two being great. One has only to consider the eminent adaptability of asbestos as a packing material and the equal excellence of steatite for the jets of gas-burners, to realise the gulf that divides them. We feel compelled to call particular attention to all that concerns this part of the invention, as it appears certain, both from the nature of the process and by the special stress laid upon it by the patentee, that the degree of novelty and efficiency of the diaphragm will largely determine the success of the process technically and financially.

One further piece of information was communicated to the meeting referred to above which cannot be wholly overlooked in a consideration of the possible future of the invention. This is the statement that an anode has been devised which is far better than any of its forerunners. It is to be regretted that no inkling of the nature of this anode was given, as the attainment of one that is at once cheap, of high conductivity, and sufficiently refractory to resist the disintegrating effect of the products of electrolysis in high degree, would be a considerable achievement.

In order to gain some idea of the particular merits of this anode, reference must again be made to the specification itself. There it is stated that the anode consists of a copper or other metal substructure, to which the carbon, after having been coppered, is soldered. No doubt by this means good conductivity at first is obtained, but as no method is mentioned of protecting the union thus formed from corrosive influences its continued utility seems improbable. The same process may be adopted for the cathode, but a similar objection applies, though in less degree. It is true that at the statutory meeting reference was made to a recent improvement in the anode, but, beyond the vague general statement that some such improvement had been effected, no information bearing upon this point was forthcoming.

Passing to the remainder of the statements of the prospectus, we find it is alleged that the yield of caustic soda and chlorine is "70 per cent. of the theoretical, a satisfactory efficiency," but whether this means that 70 per cent. of the total salt is decomposed, or that 70 per cent. of the total energy is utilised, or that the bleaching power and causticity of the products of electrolysis are 70 per cent. of that demanded by theory, is left in obscurity. This is the more important, as we believe Messrs. Cross and Bevan advanced somewhat peculiar views in the case of the notorious Hermite process, as to the bleaching efficiency of the liquor produced thereby, maintaining, if we recollect rightly, that its power of decolourising fibre could not be gauged by any method of estimating its oxidising power by titration with such a common-place re-agent as arsenious acid, and claiming for it exemption from ordinary methods of chemical criticism. This ambiguity appears to have struck even the writers of the report, for in another clause they reiterate the 70 per cent. claim, with the additional information that it applies to the electro-chemical efficiency of the process. The precision of this statement is a little marred by its juxtaposition with the remarkable assertion that this efficiency is attained with "a *resistance* of not more than 5 *volts* per cell." (The italics are ours.) The meaning is, of course, obvious, but the looseness of phraseology casts a doubt upon other statements unprovided with their own criteria. The report recommends a demonstration of the system by means of a 40 H.P. installation.

At the statutory meeting the usual disclaimer and apology was made by the Chairman, who had little to say, and his position was backed up by the inventor, who has never "heard of a new process being demonstrated before the statutory meeting was held." Mr. Greenwood, while alluding to the wonderful new anode referred to above, and to fresh patents, did not bring forward any additional information, in the absence of which the only scientific attitude to adopt towards them is that of suspended judgment

THE FARADAY CENTENARY.

On Wednesday afternoon last, at the Royal Institution, Lord Rayleigh delivered a lecture in connection with the celebration of the centenary of Faraday's birth. The Prince of Wales presided, and amongst those present were:—Sir G. Stokes, Sir W. Thomson, Sir H. Roscoe, Sir William Grove, Sir F. Abel, Sir Frederick Bramwell, the Lord Mayor and Lady Mayoress, Sir A. Geikie, Sir Benjamin Baker, Sir Joseph Lister, and Sir F. Galton.

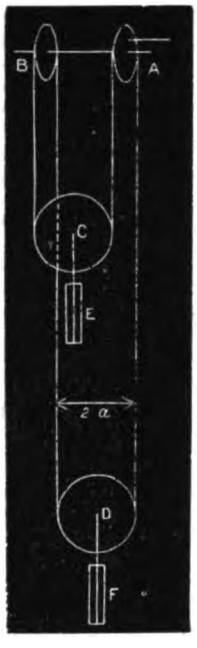
The PRINCE OF WALES, in opening the proceedings, said: I can well remember that two-and-twenty years ago I had the high privilege of presiding at a meeting here. Among others present on that occasion I remember were Sir Edward Saville, Sir Roderick Murchison, Sir Henry Holland (a very old personal friend), Dr. Bence Jones, and many others whom I recollect, but some of whom have now passed away. The object of our meeting on that occasion was to select a suitable memorial to the memory of the great Faraday. You are well aware that the fine statue by Foley, which is down in the hall below, was, we thought, a suitable memorial to the great man. As for myself, personally, I feel proud to think that in the days of my boyhood my brother and myself used to attend his chemical lectures here at this Society. We can ever remember the admirable and lucid way in which he delivered those lectures to us who were mere boys, and gave us a deep interest in chemistry, which we kept up for many years. I can only regret now that I have not the time to pursue that interesting science. To-day is a memorable day, as this year we celebrate the centenary of the birth of that great man, and I think all of us have every reason to feel grateful that two such eminent men as Lord Rayleigh and Professor Dewar have consented to give lectures on the works of Faraday. I have now only to ask Lord Rayleigh if he will give us his address.

Lord RAYLEIGH said that the man whose name and work they were met to celebrate was identified in a remarkable degree with the history of that Institution. If they could not take credit for his birth, they could in other respects hardly claim too much, for during 54 years Faraday found there his opportunity, and, for a great part of the time, his home. The simple story of his life must be known to most present. Fired by contact with the genius of Davy, he volunteered his services in the laboratory of the Institution; Davy, struck with the enthusiasm of the youth, gave him the desired opportunity, and, as had been said, found in Faraday not the least of his discoveries. The early promise was indeed amply fulfilled, and for a long period of years, by his discoveries in chemistry and electricity, Faraday maintained the renown of the Institution and the honour of England in the eyes of the civilised world. He should not attempt in the time at his disposal to trace in detail the steps of that wonderful career; the task had already been performed by able hands, and in their own "Proceedings" they had a vivid sketch from the pen of one whose absence to-day was a matter of lively regret. Dr. Tyndall was a personal friend who had seen Faraday at work, and had enjoyed opportunities of watching the action of his mind in the face of a new idea. All that he could now aim at was to recall very shortly some of Faraday's great achievements, and, if possible, estimate the position which they held in contemporary science.

Whether they had regard to eventual scientific import or practical results, the first place must be assigned to the great discovery of the induction of electric currents. He proposed first to show the experiment in something like its original form, and then pass on to variations with illustrations from the behaviour of a mode whose mechanical properties were strictly analogous. It was one of the great difficulties of his task that Faraday's discoveries were so fundamental that they had become familiar to all students of physics. The first experiment required them to establish in one coil of copper wire an electric current by completing the communication with a suitable battery; that was called the primary circuit, and Faraday's discovery was this: That at the moment of the starting or stopping of the primary current in a neighbouring circuit, in the ordinary sense of the words, completely detached, there was a tendency to induce the current to start. He had said that those two circuits were perfectly distinct, and they were distinct in the sense that there was no communication between them, but, of course, the importance of the experiment resided in this, that it proved that in some sense the circuits were not distinct; that an electric current circulating in one does produce an effect in the other, which is propagated across a perfectly blank space occupied by air, and might equally well have been occupied by vacuum. It might appear that that was a very simple and easy experiment, and of course it was so in a modern laboratory, but it was not so at the time when Faraday first made it. With all his skill, Faraday did not light upon truth without delay and difficulty. One of Faraday's biographers thus wrote:—"In December, 1824, he had attempted to obtain

Digitized by Google

an electric current by means of a magnet, and, on three occasions, he had made elaborate and unsuccessful attempts to produce a current in one wire by means of a current in another wire, or by a magnet. He still persevered, and on the 29th August, 1831, that is to say, nearly seven years after his first attempts, he obtained the first evidence that an electric current induced another in a different circuit. On September 23rd, he writes to a friend, R. Phillips, "I am busy just now again with electro-magnetism, and think I have got hold of a good thing, but cannot say ; it may be a weed instead of a fish that, after all my labour, I at last haul up." We now know that it was a very big fish indeed. Lord Rayleigh proceeded to say that he now proposed to illustrate the mechanics of the question of of the induced current by means of a model (see Figure), the first idea of which was due to Maxwell, being a combination known as Huygen's gear, invented by him in connection with the winding of clocks. Two similar pulleys, A, B, turn upon a piece of round steel fixed horizontally. Over these is hung an endless cord, and the two bights carry similar pendant pulleys, C, D, from which again hang weights, E, F. The weight of the cord being negligible, the system is devoid of potential energy ; that is, it will balance, whatever may be the vertical distance between C and D. Since either pulley, A, B, may turn independently of the other, the system is capable of two independent motions. If A, B, turn in the same direction and with the same velocity, one of the pendant pulleys, C, D, rises, and the other falls. If, on the other hand, the motions of A, B, are equal and opposite, the axes of the pendant pulleys and the attached weights remain at rest. In the electrical analogue the rotatory velocity of A corresponds to a current in a primary circuit, that of B to a current in a



secondary. If, when all is at rest, the rotation of A be suddenly started, by force applied at the handle or otherwise, the inertia of the masses E, F, opposes their sudden movement, and the consequence is that the pulley B turns *backwards*, *i.e.*, in the opposite direction to the rotation imposed upon A. This is the current induced in a secondary circuit when an electromotive force begins to act in the primary. In like manner, if A, having been for some time in uniform movement, suddenly stops, B enters into motion in the direction of the former movement of A. This is the secondary current on the break of the current in the primary circuit. The analogy of the two things was absolutely essential. So far was this the case that precisely the same argument and precisely the same mathematical equations proved that the model behaved in the way in which they had seen it behave in the experiment. That might be considered to be a considerable triumph of the modern dynamical method of including under the same head phenomena, the details of which might be so different as the impulse or relative currents. If they had a current which alternately stopped and started, and so on, for any length of time, they, as it were, produced in a permanent manner some of the phenomena of electrical induction ; and if it were done with sufficient rapidity it would be evident that something would be going on in the primary and in the secondary circuit. The particular apparatus by which he proposed to illustrate those effects of the alternating current was devised by a skilful American electrician, Prof. Elihu Thompson, and he had no doubt it would be new to many. The alternating current was led into the electromagnet by a suitable lead ; if another electric circuit, to be called the secondary circuit, was held in the neighbourhood of that, currents would be induced and might be made manifest by suitable means. Such a secondary circuit he held in his hand, which was connected with a small electric glow lamp. If a current of sufficient intensity were induced in that secondary circuit it would pass through the lamp, which would be rendered incandescent if it were of sufficient strength. (*Illustrating.*) It was perfectly clear there was no conjuring there ; the incandescent lamp brightened up. One of the first questions which presented itself was, what would be the effect of putting something between? Experimenting with a glass plate, he showed there was no effect, but when they tried a copper plate the lamp went completely out, showing that the copper plate was an absolute screen to the effect, whatever it might be. Experiments of that kind, of course in a much less developed and striking form, were made by Faraday himself, and must be reckoned amongst some of his greatest discoveries.

Before going further, he might remark on what strong evidence they got in that way of the fact that the propagation of the electric energy which, having its source in the dynamo downstairs, eventually illuminated that little lamp, that the path of the electric energy was not merely along the wires, but was capable of bridging over and passing across a space free from all conducting material, and which might be air, glass, or, equally well, vacuum. Another effect, something like the same kind, of a striking nature, devised by Prof. Elihu Thomson, consisted in the repulsive effect which occurred between the primary current circulating around a magnet and the induced current in a single hoop of aluminium wire. Illustrating this by experiment, he showed that the repulsion was so strong as to throw the wire up a considerable height. Those effects were commonly described as dependent upon the mutual induction between two distinct circuits, one being that primarily excited by a battery or other source of electricity, while the other occurred in a detached circuit. Many surprising effects, however, depended on the reactions which took place at different parts of the same circuit. One of these he exhibited by the decomposition of water.

About the time of the experiments of which he had been speaking were made, Faraday evidently felt uneasiness as to the soundness of the views about electricity held by his contemporaries, and to some extent shared by himself, and he made elaborate experiments to remove all doubt from his mind. He re-proved the complete identity of the electricity of lightning and of the electricity of the voltaic cell. He evidently was in terror of being misled by words which might convey a meaning beyond that which facts justified. Much use was made of the term "poles" of the galvanic battery. Faraday was afraid rather of the meaning which might be attached to the word "pole," and he introduced a word since generally substituted, "electrode," which meant nothing more than the way or path by which the electricity was led in. "Electric fluid" was a term which Faraday considered dangerous, as meaning more than they really knew about the nature of electricity, and as was remarked by Maxwell, Faraday succeeded in banishing the term "electric fluid" to the region of newspaper paragraphs.

Diamagnetism was a subject upon which Faraday worked, but it would take him too long to go into that subject, though he must say a word about it. Faraday found that whereas a disc of iron or nickel or cobalt, when placed near a magnet or combination of magnets, would be attracted to the place where the magnetic force was the greatest, the contrary occurred if for the iron was substituted a corresponding mass of bismuth or many other substances. The experiments in diamagnetism were of a microscopic character, but he would like to illustrate one position of Faraday's, developed years afterwards by Sir Wm. Thomson, and illustrated by him in many beautiful experiments, only one of which he now proposed to bring before them. Supposing they had two magnetic poles, a north pole and a south pole with an iron ball between them, being free to move along a horizontal line, then, according to the rule he had stated, the iron ball would seek an intermediate position, the place at which the magnetic force was the greatest. Consequently, if the iron ball be given such a position, they would find it tended with considerable force to a central position of a equilibrium ; but if, instead of using opposite poles, they used two north poles, they would find that the iron ball did not tend to the intermediate position, because that was not the position in which the magnetic force was the greatest. At that position there was no magnetic force, and one completely neutralised the action of the other. The greatest force would be a little way out, and that, according to Faraday's observations, systematised and expressed in the form of mathematical law by Sir Wm. Thomson, was where the ball would go. (*This was illustrated by experiment.*)

The next discovery of Faraday to which he proposed to call attention was one of immense significance from a scientific point of view, the consequences of which were not even yet fully understood or developed. He referred to the magnetisation of a ray of light, or what was called in more usual parlance the rotation of the plane of polarisation under the action of magnetic force. It would be hopeless to attempt to explain all the preliminaries of the

Digitized by Google

experiment to those who had not given some attention to those subjects before, and he could only attempt it in general terms. It would be known to most of them that the vibrations which constituted light were executed in a direction perpendicular to that of the ray of light. By experiment he showed that the polarisation which was sufficient to pass the first obstacle was not sufficient to pass the second, but if by means of any mechanism they were able, after the light had passed the first obstacle, to turn round the vibration, they would then give it an opportunity of passing the second obstacle. That was what was involved in Faraday's discovery. As he had said, the full significance of the experiment was not yet realised. A large step towards realising it, however, was contained in the observation of Sir William Thomson, that the rotation of the plane of polarisation proved that something in the nature of rotation must be going on within the medium when subjected to the magnetising force, but the precise nature of the rotation was a matter for further speculation, and perhaps might not be known for some time to come.

When first considering what to bring before them he thought, perhaps, he might include some of Faraday's acoustical experiments, which were of great interest, though they did not attract so much attention as his fundamental discoveries. He would only allude to one point which, as far as he knew, had never hardly been remarked, but which Faraday recorded in his acoustical papers. It related to a phenomenon capable of observation which he described on the seashore, that if during a strong, steady wind on a smooth sandy shore with enough water on it from a receding tide, there might be observed in the place where the surface was not broken by stones, the water suddenly undulates, leaving waves with ridges which were not parallel to the course of the wind. When he first read that statement, many years ago, he was a little doubtful as to whether to accept the apparent meaning of Faraday's words. He knew of no suggestion of an explanation of the possibility of waves of that kind being generated under the action of the wind, and it was, therefore, with some curiosity, that some two or three years ago at a French watering place he went out at low tide, on a suitable day when there was a good breeze blowing, to see if he could observe anything of those waves described by Faraday. For some time he failed to observe the phenomenon, but after some time he was perfectly well able to recognise them. He mentioned that as an example of Faraday's extraordinary powers of observation, and even now he doubted whether anybody but himself and Faraday had ever seen that phenomenon.

Many matters of minor and theoretic interest were dealt with by Faraday, and reprinted by him in his collective works. He was reminded of one the other day by a lamentable accident which occurred owing to the accidental breaking of a paraffin lamp. Faraday called attention to the fact, though he did not suppose he was the first to notice it, that, by a preliminary preparation of the lungs by a number of deep inspirations and expirations, it was possible so to aërate the blood as to allow of holding the breath for a much longer period than without such a preparation would be possible. He remembered some years ago trying the experiment, and running up from the drawing-room to the nursery of a large house without drawing any breath. That was obviously of immense importance, as Faraday pointed out, in the case of danger from suffocation by fire, and he thought possibly the accident to which he alluded might have been spared had the knowledge of the fact to which Faraday drew attention been more generally used.

The question had often been discussed as to what would have been the effect upon Faraday's career of discovery had he been subjected in early life to mathematical training. The first thing that occurred to him about that, after reading Faraday's works, was that one would not wish him to be anything different to what he was. If the question must be discussed, he supposed they would have to admit that he would have been saved much wasted labour, and would have been better *en rapport* with his scientific contemporaries if he had had elementary mathematical instruction. But mathematical training and mathematical capacity were two different things, and it did not at all follow that Faraday had not a mathematical mind. Indeed some of the highest authorities had held (and there could be no higher authority on the subject than Maxwell) that his mind was essentially mathematical in its qualities, although they must admit they were not developed in a mathematical direction. With these words he would conclude: "The way in which Faraday made use of his idea of lines of force in co-ordinating the phenomena of electric induction shows him to have been a mathematician of high order, and one from whom the mathematicians of the future may derive valuable and fertile methods."

Sir William Thomson moved a cordial vote of thanks to Lord Rayleigh for his delightful lecture, which was seconded by Sir George Stokes, and was carried unanimously.

Lord Rayleigh briefly replied.

Sir Frederick Bramwell read letters from Prof. Tyndal and other gentlemen expressing their regret at not being able to be present, and introduced to the Prince of Wales several distinguished foreign *savants* who had been elected members of the Institution. The Prince of Wales delivered the diploma of membership to the newly-elected members, and the proceedings closed with a vote of thanks to the Prince for presiding.

Amongst the distinguished foreign *savants* upon whom the honorary membership of the Institution have been conferred are MM. Berthelot, A. Cornu, Mascart, and Louis Pasteur; Profs. Bunsen, von Helmholtz, von Hoffmann, and Virchow; Profs. J. P. Cooke, Dana, and Simon Newcomb, of the United States; Profs. Canizzaro and Tacchini, of Rome; Prof. Thomsen, of Copenhagen; Prof. Thalen, of Upsala; Prof. Mendeleef, of St. Petersburg; Prof. Marignac, of Geneva; and Prof. Van der Waals.

A STUDY OF THE PLANTÉ LEAD-SULPHURIC ACID-LEAD PEROXIDE CELL, FROM A CHEMICAL STANDPOINT.*

PART I.

BY G. H. ROBERTSON.

The author, in the introduction, states that though, since Frankland in 1883 published his first "Contribution to the Chemistry of Storage Batteries," the capabilities of the Planté cell have been well tested and are now thoroughly understood, there is still considerable uncertainty as to the precise nature of the chemical changes which attend their use; and that it was principally to study the part played by the electrolyte that the investigation the results of which are recorded in this Paper was instituted about a year ago at the Central Institution, at Dr. Armstrong's suggestion, as McLeod's observations on the electrolysis of sulphuric acid solutions led to the supposition that the changes occurring in the acid were probably less simple than was commonly supposed. This supposition was verified.

The first section of the Paper deals with the nature of the lead salt formed during discharge. It is pointed out that, as is well known, red lead varies considerably in composition, generally containing a smaller proportion of peroxide than is represented by the formula $Pb_3O_4 = PbO_2 2PbO$; and that with nitric acid it behaves as though it were a mixture of the two oxides, the nitric acid always dissolving out the monoxide. There is no reason why sulphuric acid should not behave similarly, and, since lead sulphate is but very slightly soluble, red lead may be expected always to yield a corresponding sulphate, *i.e.*, a mixture of peroxide and sulphate, containing an amount of sulphate corresponding to the amount of monoxide originally present in combination with the peroxide. At Dr. Armstrong's request a number of experiments were made at the Central Institution (long prior to the reading of Messrs. Gladstone and Hibbert's Papers) by two students, Messrs. Briggs and Ingold, on various samples of red lead, with the result that the sulphate formed always corresponded to the monoxide originally present.

As no proof of the existence of a definite homogeneous sulphate corresponding to red lead can be afforded by analysis alone, evidence must be obtained that the product differs in some of its properties from a mixture. It was to be expected that the E.M.F. of an oxysulphate would differ from that of a corresponding mixture of sulphate and peroxide, and have some definite value; therefore pastes were made of peroxide of lead, peroxide of lead and sulphate, in the proportions of 1 to 1 and 1 to 2, and also from the product obtained by treating red lead with dilute sulphuric acid (1 to 5). Experiments made with these pastes showed that there was a difference of degree only between the red lead pastes and the mixtures, and that the lowering of the E.M.F. appeared to depend rather on the intimacy of the mixture, and consequent thorough coating of the peroxide granules with sulphate, than on the proportion of sulphate present. Mr. Desmond Fitzgerald had already shown, in 1887, at the Institution of Electrical Engineers, that the mere admixture of lead sulphate with peroxide of lead produces a lowering of the E.M.F.

With regard to Frankland's observations respecting the colour of the product formed on the peroxide plate during discharge and the reducibility of the sulphate, the author points out that the colour is due to the incomplete reduction of the peroxide, owing probably to the almost complete blocking up by lead sulphate of the pathways by which the current travels through the electrolyte in the paste; that careful examination of the plugs from a discharged cell shows that the base consists of practically unaltered peroxide of lead, and that the surface, which is rich in $PbSO_4$, is really a mass of partially reduced granules of peroxide of lead which are coated with sulphate. Also, though pure lead sulphate is very difficult to reduce, it is very well known that mixtures of lead sulphate and peroxide of lead, or other conducting substances, are reduced with comparative ease, and

* Abstract of a Paper read before the Royal Society, June 11, 1891.

Digitized by Google

it is very intimate mixtures of this nature which have to be dealt with as a rule in charging a cell.

In conclusion, the author points out :—

That neither chemical nor electrical tests give any ground for supposing that any other sulphate than the ordinary white $PbSO_4$ is concerned in the interactions occurring in the cell.

That were the sudden lowering of the E.M.F. caused by a change in the nature of the chemical compounds formed on the plates, it is very difficult to account for the very rapid recovery of the E.M.F. exhibited by an apparently discharged cell.

In the second section the electrolyte is dealt with, and, after referring to the work of Berthelot, Richarz, Schöne, Traube, and others on the electrolysis of sulphuric acid solutions, the author describes experiments made to test the effect of the addition of sodium sulphate to the electrolyte, as, from information received from Mr. Barber Starkey, it seemed probable that the different behaviour of cells containing sodium sulphate was due to the catalytic action of this salt on the hydrogen dioxide always found in electrolysed acid of the strength used in batteries, and which is probably formed by secondary action from persulphuric acid.

Mr. Preece most kindly aided the investigation by allowing experiments to be carried out at the General Post Office, where one-half of the secondary cells contain 1 per cent. of sodium sulphate and the other half ordinary dilute acid, specific gravity 1180. He also put at the disposal of the author the records of the behaviour of the cells, and as they showed that there was much less sulphating with sodium sulphate, as shown by the specific gravity never falling to the same extent as in the plain cells, but that the general character of the changes in temperature and in specific gravity during charge and discharge were the same in both types of cell, and of the nature which the work of Prof. Ayrton and others has rendered familiar to all, it was only the distribution of temperature and of specific gravity which was investigated, and this was found to be very irregular.

It was found that the addition of sodium sulphate, in about the proportion of 1 per cent:, to freshly electrolysed acid, or during electrolysis, always produced a diminution in the total quantity of "active oxygen," and brought the amount present in the plain cells down almostly exactly to that found in the sodium sulphate cells.

Experiments on the growth of the "peroxides" were carried on during five charges and discharges, but only the figures relating to the first discharges are given, as the other charges and discharges are mere repetitions. The peroxides form at once, then undergo a diminution, and then increase again. The alteration in the totals is due mainly to actions occurring at the lead plate in the plain cell, as at the peroxide plate the amounts steadily increase ; in the sodium sulphate electrolyte there is a diminution at both plates, followed by an increase.

Determinations were made of the amounts of "active oxygen" present as persulphuric acid and hydrogen dioxide respectively, and it was established that acid taken from the cell reduced peroxide of lead. The presence of hydrogen dioxide being thus established, both directly and indirectly, its effect on the E.M.F. of a cell was tested. It was found that, while its addition to the acid in the case of a lead peroxide couple in dilute sulphuric acid produced an annulment or reversal of the E.M.F., the introduction of hydrogen dioxide into the body of the peroxide paste produced an increase of E.M.F. in the case of a platinum-lead peroxide couple. The latter experiment was made with a view of reproducing, if possible, the conditions of a cell which is started discharging directly it is fully charged, and in which the persulphuric acid formed at the positive during charge may be supposed to break up with the formation of hydrogen dioxide on the cessation of the charging current, thereby increasing the normal E.M.F. of the cell.

The cause of the pink colour of the acid noticed by Mr. Crompton and others was investigated, and found to be permanganic acid, formed probably from the manganese present in commercial lead.

In conclusion, the author points out :—

That "peroxides" are found in appreciable quantities in the electrolyte during charge and discharge ;

That their influence must not be neglected in considering the behaviour of the Planté cell ;

And that it is to the electrolyte rather than to the plates that attention must be directed if any considerable improvement is to be effected.

PART II.

A DISCUSSION OF THE CHEMICAL CHANGES OCCURRING IN THE CELL.*

BY H. E. ARMSTRONG, F.R.S., AND G. H. ROBERTSON.

The authors arrive in this Paper at the following conclusions :—

1. That the cooling observed in the Planté cell can only be explained as resulting from the dissociation of the dilute sulphuric acid ; and as the values given by Messrs. Ayrton, Lamb, Smith, and Woods are in practical agreement with those calculated on the assumption that the acid used is sulphuric acid itself, H_2SO_4, that in all probability such acid and not the dilute acid contained in the cell is operative throughout.

2. That the observed loss in efficiency cannot be due to temperature changes, as these arise through actions occurring out of circuit.

3. That it is difficult from a comparison of calculated with observed values of the E.M.F. to arrive at any final conclusion as to the exact nature of the changes which take place in the cell. On the assumption that sulphating occurs at both plates in circuit und under the influence of H_2SO_4, the calculated value is considerably too high ; while, if sulphating occur only at the lead plate, the value calculated is far too low.

4. That a counter E.M.F. of about 0·5 volt would account for the observed departure from the highest calculated value. As peroxides are always present in the electrolyte, it is conceivable that such a counter E.M.F. may exist ; moreover, there is also the possible influence of the lead support to be considered.

5. That the observed loss of efficiency is to be attributed to the formation of peroxides in the electrolyte, and to the excessive sulphating occurring chiefly at the peroxide plate in the local circuit existing between the support and the paste.

* Abstract of a Paper read before the Royal Society, June 11, 1891.

ON ELECTRICAL EVAPORATION.*

BY WILLIAM CROOKES, F.R.S.

It is well known that when a vacuum tube is furnished with internal platinum electrodes, the adjacent glass, especially near the negative pole, speedily becomes blackened, owing to the deposition of metallic platinum. Whilst a solid body like platinum requires an intense heat to enable its upper stratum of molecules, to pass beyond the sphere of attraction of the neighbouring molecules experiment shows that a very moderate amount of negative electrification superadds sufficient energy to enable the upper stratum of metallic molecules to fly beyond the attractive power of the rest of the metal. I have recently made some experiments upon the evaporation of different substances under the electric stress.

Evaporation of Water.—A delicate balance was taken, and two very shallow porcelain dishes were filled with acidulated water and balanced on the pans. Dipping into each dish—touching the liquid, but not the dish—was a platinum wire, one connected with the induction coil and the other insulated.

It was found that *negatively* electrified water lost in 1½ hours 1/1000th part of its weight more than did insulated water. This experiment shows that the disturbing influence which assists evaporation is peculiar to the negative pole, even at atmospheric pressures.

The metal cadmium was next experimented upon.

Evaporation of Cadmium.—If the flying-off of the metal of the negative pole is similar to evaporation or volatilisation the operation should be accelerated by heat.

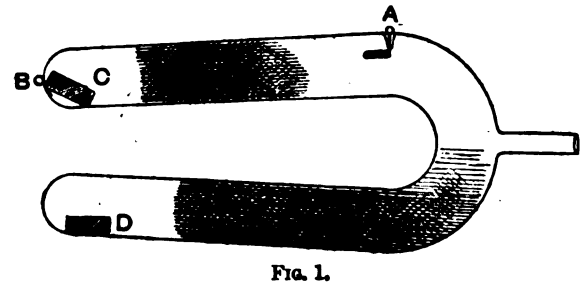


FIG. 1.

A tube was made as shown in Fig. 1. A and B are the platinum poles sealed through the glass. C and D are two blocks of metallic cadmium of the same size and weight. The piece C is in contact with the pole B, which in the experiment was always kept negative, the pole A being positive. When the exhaustion was such that the passage of the current gave green phosporescence over the glass, heat was applied simultaneously to both ends of the U-shaped tube by means of a gas-burner and air-bath, so that one piece of cadmium was at the same temperature as the other. The current was then applied and was kept on for about an hour, and it was remarkable that no metal was deposited in the neighbourhood of the positive pole, the surrounding portion of the tube being quite clean, while the corresponding part of the other limb of the tube, having no electrodes, was thickly coated, the appearance being shown in the drawing.

As the temperature was high, metal had distilled off from both

* Abstract of a Paper read before the Royal Society, June 11, 1891.

Digitized by Google

lumps ; hence there was no visible difference in the amount of the deposit in the two sides. It is evident that, to render the electrical action most visible, the temperature should be kept short of the normal volatilising point.

In the next experiment an exactly similar tube was used ; the vacuum was such that the green phosphorescence of the glass was well seen, the temperature was kept just below the melting point of cadmium, and the current was kept on for an hour. On examining the tube at the end of this time, the appearance was as seen in Fig. 2. A considerable deposit had taken place on the end of the tube near the negative pole, the space round the positive pole was clear, while in the limb of the tube where no electricity had been passing only a very little deposit of metal was seen, as shown in the figure.

In these experiments no estimation was made of the weight of metal removed. To render the experiment quantitative, and at the same time to remove any disturbing effect that might be caused by heating at the point of indifferent contact, the following experiments were made :—

A U-shaped tube had a platinum pole sealed in each end. Six grains of pure cadmium were put into each limb and fused round the platinum wire. The ends of the tube were then put into an air-bath, and kept at a temperature of 200°C. during the continuance of the experiment. The exhaustion remained at 0·00076mm., or 1 M. The induction current was kept going for 35 minutes. At the end of this time it was seen that most of the cadmium had disappeared from the negative pole, leaving the platinum wire clean, no metal being deposited near it, and the molecules appearing to have been shot off to a distance of about $\frac{3}{4}$in. The appearance of the positive pole was very different ; scarcely any of the cadmium had been volatilised, and the condensed metal came almost close to the pole. The tube was opened, and the remaining wires and metal were weighed. The cadmium was then dissolved off the poles in dilute acid ; the residue was washed, dried, and weighed.

	Positive pole.	Negative pole.
Original weight of cadmium	6·00 grs.	6·00 grs.
Cadmium remaining on the pole	3·65 „	0·25 „
Cadmium volatilised in 35 mins.	2·35 „	5·75 „

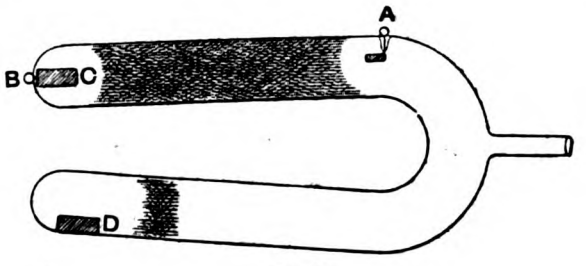

Fig. 2.

The difference between the amount of cadmium driven from the two poles having proved to be so decided, another experiment was tried in a tube so arranged that the metal could be more easily weighed before and after the experiment. In 30 minutes the experiment was stopped, and after all was cold the tube was opened and the wires weighed again. The results were as follows :—

	Positive pole.	Negative pole.
Original weight of cadmium	9·34grs.	9·38grs.
Weight after experiment.....	9·25 „	1·86 „
Cadmium volatilised in 30 min.....	0·09 „	7·52 „

Volatilisation of Silver.—Silver was the next metal experimented upon. Small lumps of pure silver were cast on the ends of platinum wires, and suspended to the inner ends of platinum terminals passing through the glass bulb. The platinum wires were protected by glass, so that only the silver balls were exposed. The whole apparatus was enclosed in a metal box lined with mica, and the temperature was kept as high as the glass would allow without softening. The apparatus was exhausted to a dark space of 3mm., and the current was kept on for 1½ hours. The weights of silver, before and after the experiment, were as follows :—

	Positive pole.	Negative pole.
Original weight of silver	18·14grs.	24·63grs.
Weight after the experiment	18·13 „	24·44 „
Silver volatilised in 1½ hours	0·01 „	0·19 „

It having been found that silver volatilised readily from the negative pole in a good vacuum, experiments were instituted to ascertain whether the molecules of metal shot off from the pole were instrumental in producing phosphorescence. A glass apparatus was made as shown in Fig. 3. A pear-shaped bulb of German glass has, near the small end, an inner concave negative pole, A, of pure silver, so mounted that its inverted image is thrown upon the opposite end of the tube. In front of the pole is a screen of mica, having a small hole in the centre, so that only a narrow pencil of rays from the silver pole can pass through, forming a bright spot of phosphorescence, D, at the far end of the bulb. The exhaustion was pushed to a high point, 0·00068mm., or 0.9 M. The current from an induction coil was allowed to pass continuously for some hours, the silver pole being kept negative, so as to drive off a certain portion of the silver electrode. On subsequent examination it was found that the silver had all been deposited in the immediate neighbourhood of the pole, whilst at the far end of the tube the spot D, that had been continuously glowing with phosphorescent light, was practically free from silver.

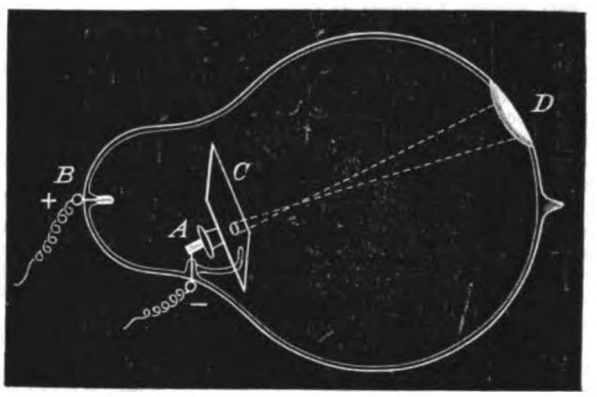

Fig. 3.
P=0·00068*mm.*
=0·9 M.

A tube was next made as shown in Fig. 4. It had two negative poles connected together, A, A′, so placed as to project two luminous spots on the phosphorescent glass of the tube. One of the electrodes, A′, was of silver, a volatile metal ; the other, A, was of aluminium, practically non-volatile. On connecting the two negative poles, A, A′, with one terminal of the coil, and the positive pole, B, with the other terminal, it was seen in the course of half-an-hour that a considerable quantity of metal had been projected from the silver negative pole, blackening the tube in its neighbourhood, while no projection of metallic particles took place from the aluminium positive pole. During the whole time of the experiment, however, the two patches of phosphorescent light, C and C′, had been glowing with exactly the same intensity, showing that the active agent in effecting phosphorescence was not the molecules of the solid projected from the poles, but the residual gaseous particles, or "radiant matter."

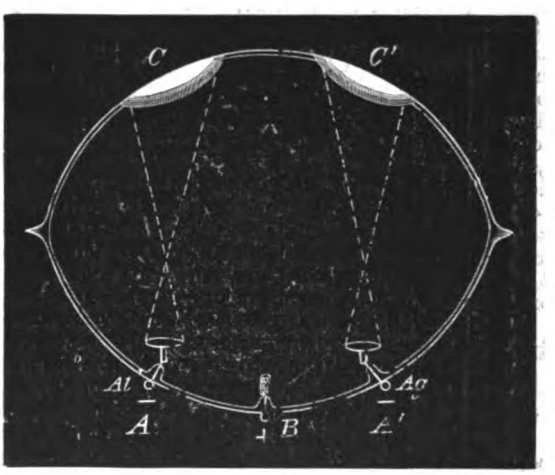

Fig. 4.
P=0·00068*mm*
=0·9 M.

If, for the negative electrode, instead of a pure metal such as cadmium or silver, an alloy was used, the different components might be shot off to different distances, and in this way make an electrical separation—a sort of fractional distillation. A negative terminal was formed of clean brass, and submitted to the electrical discharge *in vacuo* ; the deposit obtained was of the colour of brass.

Digitized by Google

throughout, and on treating the deposit chemically I could detect no separation of its component metals, copper and zinc.

If we take several liquids of different boiling points, put them under the same pressure, and apply the same amount of heat to each, the quantity passing from the liquid to the gaseous state will differ widely in each case. It was interesting to try a parallel experiment with metals, to find their comparative volatility under the same conditions of temperature, pressure, and electrical influence. It was necessary to fix upon one metal as a standard of comparison, and for this purpose I selected gold, its electrical volatility being great, and it being easy to prepare in a pure state.

An apparatus was made with four negative poles at one end and one positive pole at the other. By a revolving commutator I was able to make electrical connection with each of the four negative poles in succession for exactly the same length of time (about six seconds); by this means the variations in the strength of the current, the experiment lasting some hours, affected each metal alike. The exposed surface of the various metals used as negative poles was kept uniform by taking them in the form of wires that had all been drawn through the same standard hole in the drawplate, and cutting them by gauge to a uniform length; the actual size used was 0·8mm. in diameter, and 20mm. long. The comparison metal, gold, had to be used in each experiment; the apparatus thus enabled me to compare three different metals each time. The length of time that the current was kept on the revolving commutator in each experiment was eight hours, making two hours of electrification for each of the four negative electrodes; the pressure was such as to give a dark space of 6mm.

The following table of the comparative volatilities was in this way obtained, taking gold as = 100:—

Palladium	108·00	Platinum	44·00
Gold	100·00	Copper	40·24
Silver	82·68	Cadmium	31·99
Lead	75·04	Nickel	10·99
Tin	56·96	Iridium	10·49
Brass	51·58	Iron	5·50

In this experiment equal surfaces of each metal were exposed to the current. By dividing the numbers so obtained by the specific gravity of the metal, the following order is found:—

Palladium	9·00	Cadmium	3·72
Silver	7·88	Copper	2·52
Tin	7·76	Platinum	2·02
Lead	6·61	Nickel	1·29
Gold	5·18	Iron	0·71
Iridium	0·47		

Aluminium and magnesium appear to be practically non-volatile under these circumstances. The order of metals in the table shows at once that the electrical volatility in the solid state does not correspond with the order of melting points, of atomic weights, or of any other well-known constant.

It is seen in the above table that the electrical volatility of silver is high, while that of cadmium is low. In the two earlier experiments, where cadmium and silver were taken, the cadmium negative electrode in 30 minutes lost 7·52 grs., whilst the silver negative electrode in 1½ hours only lost 0·19 gr. This apparent discrepancy is easily explained by the fact (already noted in the case of cadmium) that the maximum evaporation effect, due to electrical disturbance, takes place when the metal is at or near the point of liquefaction. If it were possible to form a negative pole *in vacuo* of molten silver, then the quantity volatilised in a given time would be probably much more than that of cadmium.

Gold having proved to be readily volatile under the electric current, an experiment was tried with a view to producing a larger quantity of the volatilised metal. A tube was made having at one end a negative pole cemposed of a weighed brush of fine wires of pure gold, and an aluminium pole at the other end. The tube was exhausted and the current from the induction coil put on, making the gold brush negative; the resistance of the tube was found to increase considerably as the walls became coated with metal, so much so that, to enable the current to pass through, air had to be let in after a while, depressing the gauge ½mm. The weight of the brush before experiment was 35·4949 grs. The induction current was kept on the tube for 14½ hours; at the end of this time the tube was opened and the brush removed. It now weighed 32·5613, showing a loss of 2·9327 grs. When heated below redness the deposited film of gold was easily removed from the walls of the tube in the form of very brilliant foil. After having been subjected to electrical volatilisation, the appearance of the residual piece of gold under the microscope, using a ¼in. object glass, was very like that of electrolytically deposited metal, pitted all over with minute hollows.

This experiment on the volatilisation of gold having produced good coherent films of that metal, a similar experiment was tried, using a brush of platinum as a negative electrode. On referring to the table it will be seen that the electrical volatility of platinum is much lower than that of gold, but it was thought that by taking longer time a sufficient quantity might be volatilised to enable it to be removed from the tube. The vacuum tube was exhausted to such a point as to give a dark space of 6mm., and it was found, as in the case of gold, that as a coating of metal was deposited upon the glass the resistance rapidly increased, but in a much more marked degree, the residual gas in the tube apparently becoming absorbed as the deposition proceeded. It was necessary to let a little air into the tube about every 30 minutes, to reduce the vacuum. This appears to show that the platinum was being deposited in a porous spongy form, with great power of occluding the residual gas. Heating the tube when it had become in this way non-conducting liberated sufficient gas to depress the gauge of the pump 1mm., and to reduce the vacuum so as to give a dark space of about 3mm. This gas was not re-absorbed on cooling, but on passing the current for ten minutes the tube again refused to conduct, owing to absorption. The tube was again heated, with another liberation of gas, but much less than before, and this time the whole was re-absorbed on cooling. The current was kept on this tube for 25 hours; it was then opened, but I could not remove the deposited metal except in small pieces, as it was brittle and porous. Weighing the brush that had formed the negative pole gave the following results:—

	Grains.
Weight of platinum before experiment	10·1940
,, after experiment	8·1570
Loss by volatilisation in 25 hours	2·0370

Another experiment was made similar to that with gold and platinum, but using silver as the negative pole, the pure metal being formed into a brush of fine wires. Less gas was occluded during the progress of this experiment than in the case of platinum. The silver behaved the same as gold, the metal deposited freely, and the vacuum was easily kept at a dark space of 6mm. by the very occasional admission of a trace of air. In 20 hours nearly 3 grs. of silver were volatilised. The deposit of silver was detached without difficulty from the glass in the form of brilliant foil.

PHYSICAL SOCIETY.

At the meeting of the Physical Society, on Friday last, Prof. AYRTON read a Paper by himself and Dr. Sumpner,

"On Alternate Current and Potential Difference Analogies in the Methods of Measuring Power."

In a Paper read before the Society in March last, the authors pointed out that for every method of measuring power in which readings of volts and amperes were taken, other methods in which amperes were read instead of volts, and volts instead of amperes, could be devised. More recently, Dr. Fleming had, by a transformation of a formula given by the authors in a communication made to the Royal Society on the measurement of power by three voltmeters, given the analogue in which three ammeters were employed. The two arrangements are represented in Figs. 1 and 2,

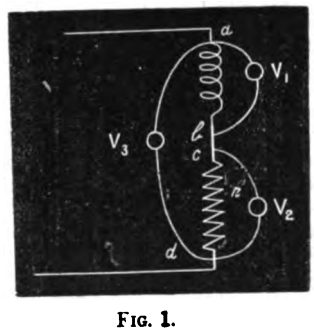

FIG. 1.

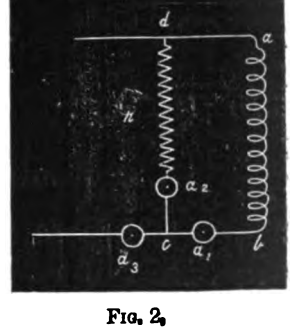

FIG. 2.

whilst Fig. 3 shows a modification of Dr. Fleming's method (Fig. 2), in which the current in the non-inductive resistance r is measured by the aid of a voltmeter, V, across its terminals. This obviates the necessity of putting an electro-magnetic instrument in what should be a non-inductive circuit. The formula for the mean watts spent in the circuit $a\ b$, Figs. 1 and 2, are respectively

$$W = \frac{1}{2}\frac{1}{r}(V_3^2 - V^2 - V_2^2) \text{ and } W = \frac{r}{2}(A_3^2 \quad A_1^2 = A_2^2)$$

Mr. Blakesley's method of measuring power by a split dynamometer was shown to be analogous to the original electrometer method, in which the difference of the two readings was proportional to the power, and Blondlot and Currie s double electrometer

Digitized by Google

method was shown to be the analogue of the ordinary wattmeter. The wattmeter was defective in the fact that a solenoidal coil was inserted in a nominally non-inductive circuit. The error thus introduced is, as was shown by one of the authors some years ago, expressed by the formula—

$$\frac{\text{Apparent watts}}{\text{True watts}} = \frac{1+\tan\theta\tan\phi}{1+\tan^2\phi}$$

where θ is the phase angle between the current and E.M.F. in the circuit in which the power is to be measured, and ϕ the phase angle for the approximately non-inductive circuit. It is now proved that the same formula expresses the error in any of the methods where resistances not wholly non-inductive are used.

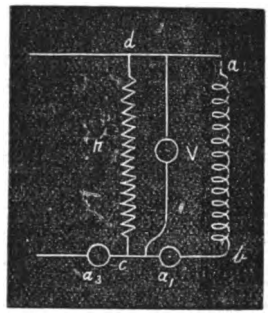

FIG. 3.

As is well-known, Mr. Blakesley has applied his split-dynamometer to the measurement of phase differences between two currents; and an analogous method of finding the phase difference between two potential differences is described in the Paper. In this method a high resistance split-dynamometer, such as suggested by Mr. Rimington for measuring power, is employed. Blondlot and Currie's double electrometer could also be used for the same purpose. Numerous diagrams illustrating the various analogies accompany the Paper.

DISCUSSION.

Prof. S. P. THOMPSON enquired whether hot-wire voltmeters could be employed to measure the various potential differences, without introducing error?

In reply, Prof. AYRTON said that the error introduced by the self-induction of these instruments was generally negligible, yet the fact that they required considerable current was a disadvantage, and as these currents were not always in the same phase as those in other circuits, troublesome corrections were sometimes necessary. Electrostatic instruments were preferable.

Prof. ADAMS said he was glad to hear that the inductance of Cardew voltmeters introduced no serious error, for they were very convenient instruments to use.

Dr. Oliver Lodge exhibited and described two forms of clocks for pointing out the direction of the motion of the earth through space.

Some experiments with Leyden jars were then shown by Dr. Lodge. The first one was with resonant jars, in which the discharge of one jar precipitated the overflow of another, when the lengths of the jar circuits were properly adjusted or tuned. The latter jar was entirely disconnected from the former, and was influenced merely by electro-magnetic waves emanating from the discharging circuit. Lengthening or shortening either circuit prevented the overflow. Correct tuning was, he said, of great importance in these experiments, for only a dozen or more oscillations occurred before the discharge ceased. The effect could be shown over considerable distances. In connection with this subject Mr. Blakesley had called his attention to an observation made by Priestly many years ago, who noticed that when several jars were being charged from the same prime conductor, if one of them discharged, the others would sometimes also discharge, although they were not fully charged. This, he, Dr. Lodge, thought might be due to the same kind of influence which he had just shown to exist. The word *resonance*, he said, was often misunderstood by supposing it always had reference to sound, and as substitutes he thought that the words *syntonic* or *syntony* might be allowed.

The next experiment was to show that wires might be tuned to respond to the oscillation of a jar discharge, just as a string could be tuned to respond to a tuning fork. A thin stretched wire about 50 or 60 feet long, suspended in the room, was connected to the knob of a jar and another parallel one to its outer coating, and, by varying the length of an independent discharging circuit, a glow was caused to appear near the remote halves of the stretched wires, at each discharge. Each of the wires thus acted like a stopped organ pipe, the remote ends, which were insulated, being the nodes at which the variations of pressure are greatest. By using long wires he had observed a glow on portions of them with the intermediate parts dark; this corresponded with the first harmonic, and, by measuring the distance between two nodes, he had determined the wave length of the oscillations. The length so found did not agree very closely with the calculated length, and the discrepancy he thought due to the specific inductive capacity of the glass not being the same for such rapidly alternating pressures as for steady ones. He also showed that the electric pulses passing along a wire could be caused (by tuning) to react on the jar to which it was connected, and cause it to overflow even when the distance from the outside to the inside coating was about 8in. During this experiment he pointed out that the noise of the spark was greatly reduced by increasing the length of the discharging circuit. The same fact was also illustrated by causing two jars to discharge into each other, spark gaps being put both between their inner and outer coatings, so as to obtain "A" sparks and "B" sparks. By putting on a long "alternative path" as a shunt to the B spark gap, and increasing that gap, the noise of the A spark was greatly reduced. He had reason to believe that the B spark was a quarter phase behind the A spark, but the experimental proof had not been completed.

He next described some experiments on the screening of electromagnetic radiation, in which a Hertz resonator was surrounded by different materials. He had found no trace of opacity in insulators, but the thinnest film of metal procurable completely screened the resonator; cardboard rubbed with plumbago also acted like a nearly perfect screen. In connection with resonators, he exhibited what he called a *graduated electric eye* or an electric harp (Fig. 4),

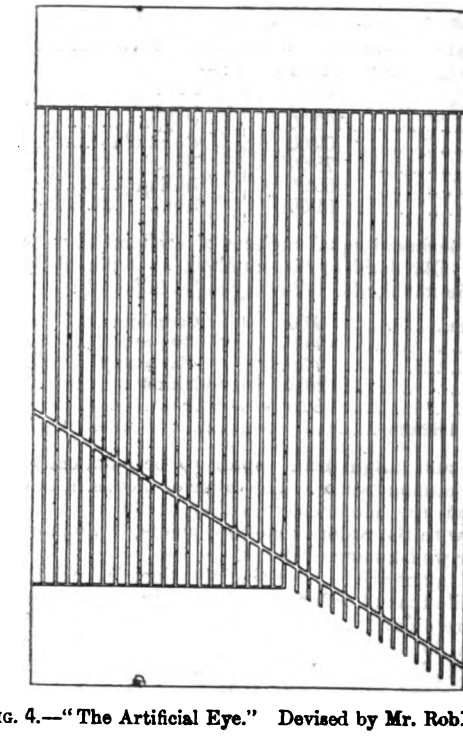

FIG. 4.—"The Artificial Eye." Devised by Mr. Robinson.

devised by his assistant, Mr. Robinson, in which strips of tinfoil of different lengths are attached to a glass plate, and have spark gaps at each end, which separate them from other pieces of foil. One or other of the strips would respond according to the frequency of the electro-magnetic radiation falling upon it.

DISCUSSION.

Mr. BLAKESLEY asked whether the tuning of the resonant jars needed readjustment when the distance between their circuits was varied, for, according to theory, the mutual induction should diminish the self-induction of the primary, and cause its oscillations to be more rapid. If this was true, the method might be used for getting rapid oscillations. He also inquired whether the glow would appear in the same position on the two stretched wires if their ends were joined?

Dr. SUMPNER wished to know how the resistances, inductances, and capacities of the circuits and jars were determined, and whether any evidence of irregular distribution of the charges on the tinfoil had been noted, since such irregularity might account for the apparent change in the capacity. With reference to the overflowing of a jar caused by connecting up a certain length of wire in the discharging circuit, he asked whether the overflow did not prove the existence of a higher potential than that which originally existed between the coatings of the jar, and, if so, where did the excess energy come from?

Dr. THOMPSON asked if it would be possible to make a wire circuit analogous to an open organ pipe by putting sheets of metal on the ends of the wires?

Dr. LODGE, in reply, said Mr. Blakesley's suggestion was an important one, but he had not observed that any change in the adjustment was necessitated by varying the distance between the resonating circuits. Neither

Digitized by Google

had he noticed any glow on wires joined to form a single loop, but this might be possible if the wires were long enough to give harmonies.

In answer to Dr. Sumpner, he said that the capacities were difficult to determine, for with such rapid oscillations the coatings were virtually enlarged. Lord Rayleigh had shown how to calculate the inductances, and the resistances he had practically measured by his alternative path experiments. The overflow of jars, he thought, was caused by the charges in some way concentrating on the edges of the foil, thus causing a kind of flood tide at which the overflow occurred.

The PRESIDENT asked Dr. Lodge what his views were as to the cause of the opacity of ebonite to light. Was it due to a selective absorption which cut off only the rays to which the eye was sensitive, or was the ordinary explanation, that it contained impurities which were conducting, and hence acted as screens, likely to be correct? Another possible explanation was that the motion of the ether particles may be in three dimensions, and light be due to the projection of this motion on a plane perpendicular to the ray, whilst electro-magnetic induction might be due to the other component.

Dr. LODGE said he believed that ebonite was not opaque, because of conducting particles being present, and was inclined to think that it acted more like ground glass, in which the opacity was due to internal reflections. Such a substance would only be opaque to vibrations whose wavelength were comparable with the size of the particles.

LEGAL INTELLIGENCE.

Allison v. City and South London Railway.

In the Chancery Division on Tuesday and Wednesday the case of Allison v. City and South London Railway Company came before Mr. Justice Kekewich. This was an action brought by the Trustees of the Stockwell Orphanage, Clapham-road, against the City and South London Railway Company for damages, and an injunction to restrain the Company from working three engines of 400 H.P. which were used for driving the dynamos for the purpose of working the electric railway. The plaintiffs' case was that the vibration and noise caused by the engines, together with the condensed steam, created such a nuisance as no statutory powers conferred on the Company could possibly cover. The plaintiffs further contended that if certain appliances had been used by the Company the nuisances might have been, if not absolutely abated, greatly mitigated. The defendant Company denied negligence in the use of their engines, and contended that in all they had done they had acted under statutory powers.

Mr. Rigby, Q.C., Mr. Renshaw, Q.C., and Mr. Ingle Joyce appeared for the plaintiffs; while Mr. Cozens-Hardy, Q.C., Mr. W. Graham, and Mr. Gwynne James represented the defendant Company.

Mr. HENRY LEE, consulting engineer, of 28 years' experience, gave evidence in support of the plaintiffs' case. He said that three of the houses at the Orphanage were uninhabitable for ordinary purposes, owing to the noise and vibration caused by the engines at the defendant Company's generating station. Clouds of steam also came from the exhaust pipe, and were a great nuisance.

In cross-examination, witne s said he had not had any actual experience of electrical railways. If felt were used to put an end to the noise the vibration would remain, so as to make the houses uninhabitable. In re-examination, witness said with the present engines there would be a difficulty in reducing the vibration so that it would not be a nuisance to the adjoining premises. If different engines and different beds were used on the same site, he thought that there would be a risk of vibration. The nuisance might be abated by changing the position of the generating station and using different engines.

By the JUDGE: The vibration extended over a circular area of from 100 to 150ft.

Mrs. STIFF, the wife of one of the plaintiffs, said she had been in the habit of holding a Bible class in one of the rooms of the first house of the Orphanage. The Company commenced to run trains on Sundays in April last. The vibration felt in the room in which she held her Bible class was very disagreeable, and had a serious effect upon the members of her class. She had to abandon the room, and hold her class in the fourth house. Her private residence adjoined the railway, and had suffered from the vibration and the steam and grease which came from the exhaust pipe.

In cross-examination, the witness said her husband opposed the Bill authorising the construction of the railway when it was before Parliament, and incurred expense. Her husband had offered to sell his garden to the Company because of the nuisance of the railway.

Other evidence having been given, the case for the plaintiffs closed.

Sir B. BAKER was then called on behalf of the defendant Company. He said he had been consulting engineer to the Company ever since it was started. The works in question were erected under the immediate control of Mr. Greathead, the engineer to the Company. Mr. Greathead consulted witness and Sir J. Fowler with regard to the generating station. The engines and dynamos at the station were well constructed, and suited for the work they were intended to perform. The engines were of the most approved type. He did not agree that it would be a great improvement if the engines were not connected with the dynamos by long straps, but were worked directly in connection with the dynamos. The question of the adoption of the engine suggested by Mr. Lee was considered, and it was resolved not to have it. The beds of the engines were constructed and carried out with all due care.

In cross-examination, witness said the generating station was covered with thin plates of corrugated iron. He did not think that was the best kind of roof for keeping out the noise caused by the working of the machinery, though he would not say it was the worst. By making certain alterations in the roof it would be possible to reduce the noise.

Mr. GREATHEAD, engineer to the Company, stated that it was necessary for the defendant Company to increase their shed accommodation, because they were adding to their rolling stock to meet the traffic on the line. The engine house was designed by him, and the engines used were of the most approved type. He had visited the Orphanage, but had not noticed such noise or vibration as could be described as a nuisance to the inmates.

In cross-examination, witness said the corrugated roof of the generating station was not the best that could be devised for keeping out the noise of the engines and machinery. In consequence of the complaints at the Orphanage he went there and made an examination. He noticed some noise and vibration, and he had no doubt that they proceeded from the defendant Company's engines. On the occasion of his last visit to the Orphanage there was no substantial vibration or noise. He did not admit that any time the noise and vibration produced by the machinery caused the inmates of the Orphanage any annoyance.

Mr. BASIL MOTT, resident engineer in charge of the defendant Company's works, gave corroborative evidence.

The further hearing of the case was adjourned till Thursday.

THURSDAY, JUNE 18TH.

Mr. GEO. HOPKINS, civil engineer, stated that he visited the generating station on Friday, the 5th inst., and that he subsequently went to the Orphanage, where he detected a slight noise and vibration when the engines were at work. He believed that the noise proceeded from the open roof, doors, and windows of the engine station, and therefore he should advise the Company to try some felt. The vibration was caused by the action of the engines. To lessen the noise and vibration he should advise the Company to do away with the openings in the roof of the generating station, and to fill up certain openings in a wall near the boundary line. In cross-examination, witness admitted that he would not like to live in the first house at the Orphanage. He should object to the noise, but not to the vibration.

By his LORDSHIP: He would not like to bring up his children in the first house of the Orphanage.

Witness, in re-examination, said the defendant Company's engines were well constructed and properly worked. When he went to the Orphanage he was convinced in his own mind that he should detect both noise and vibration.

At the conclusion of the witness's evidence,

His LORDSHIP said the questions he had to try were whether there was any nuisance independently of the Parliamentary power of the defendant Company, and whether, assuming there was a nuisance, it could not be abated. The answer to the second question might depend, to some extent, on the further question, whether the Company had done all that they possibly could to prevent the nuisance. The Company's Parliamentary powers were a good defence if they satisfied the Court that they had done their very best to stop the noise and vibration. After the evidence of Mr. Hopkins it seemed to him impossible to say that the Company had done their very best, because that gentleman had suggested several possible improvements He, therefore, put it to the Company whether it would not be desirable for them to take a reasonable time to see what they could do to abate what he (the learned judge) regarded as an existing nuisance before they approached the moot point of law as to their Parliamentary powers.

Mr. COZENS HARDY said the Company were quite prepared to try felt.

His LORDSHIP remarked that Mr. Hopkins had said something might be done to abate the nuisance as regarded the noise and vibration. That gentleman was clearly of opinion that there was a great noise, going far to render the house uninhabitable. If, after the defendant Company had done their best the nuisance still remained, the question as to the Company's Parliamentary powers would arise.

Mr. COZENS HARDY said he would concede to his Lordship's suggestion. The case would, therefore, stand adjourned.

Mr. RENSHAW hoped that there would be no delay.

His LORDSHIP said the case must be disposed of between now and the 12th of August.

Mr. COZENS HARDY said if the plaintiffs had any suggestion to make the defendant Company would consider it.

Mr. RENSHAW thought that the best course would be for the defendant Company to draw up some scheme and submit it to the plaintiffs.

The case was accordingly adjourned *sine die*, with liberty to either party to apply to have it put into the list.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June* 5, 1891.

The Edison Incandescent Lamp Patent.—The matter of greatest interest now before the electrical public is the trial, just completed, of an action involving the validity of the Edison Incandescent Lamp patent. The incandescent lamp has been the subject of serious litigation in this country but once previously, namely, in the action of the Consolidated Electric Light Company (Sawyer-Man patent) *v.* the McKeesport Light Company, using the Edison lamps. Decision in this case was reached October 5th, 1889, and its result was the demolition of the Sawyer-Man claims. During the progress of this suit the Edison Company opened the counter suit that has just been tried. The preliminary steps had been

Digitized by Google

taken several years before the date mentioned, but, owing to interferences in the Patent Office and other legal complications, nothing serious was done until about the time of the McKeesport decision. Justice Bradley's opinion in this case was remarkable in that it upset the Sawyer-Man patent, and, while nominally sustaining the Edison claims, damaged them rather seriously in its decision as to the state of the art. Now the incandescent lamp question is coming to a legal decision in rather definite form. The claim on which the matter hinges is the second one of Edison's patent, the same thing that has been sustained in the English courts, to wit: the combination of carbon filament with a receiver made entirely of glass, and conductors passing through the glass, and from which receiver the air is exhausted for the purposes set forth. The attack of the Edison Company is along the line pursued in the English litigation, on the question of the great influence of Edison on the art, and his production of a high resistance carbon lamp at a time when his competitors were working with comparatively low resistance lamps. The defence is, as it has been in previous cases, lack of invention and lack of novelty in the Edison patent, considering the previous state of the art. It is undoubtedly true that the claim of the Edison Company that a high resistance carbon lamp was the first practical commercial lamp, and that Edison introduced this lamp is pretty well substantiated, but the truth to tell, the patent in the suit doesn't cover the case nearly as well as it might. Edison was in the Patent Office for several years with an application of somewhat broader character, which he was not successful in obtaining, therefore this action for infringement had to be brought on the original patent, of which the second claim is the only valuable part. The arguments of counsel for Mr. Edison were intended, in the first place, to show the insufficiency of previous lamps to meet the commercial requirements of the case; second, the importance of the modifications introduced by Mr. Edison; third, the consequent developments of the commercial incandescent lamp. The counsel for the Westinghouse Company (the real defendant in this case) have endeavoured to show, in the first place, that the use of carbon in incandescent lamps is old; that the use of an exhausted receiver is old; that the use of platinum leading wires sealed through glass and an incandescing conductor of considerable resistance had been anticipated at the time the application for this Edison patent was filed. The first point is easily shown. The exhausted receiver had been shown pretty completely both by King and in the Adams lamp, which, unfortunately for the defendant, had not been published or patented. The high resistance claim had been to a certain extent anticipated by the platinum lamp of Mr. Edison himself, and the suggestions of Lane-Fox. While it is undoubtedly true that Edison was the pioneer of carbon high-resistance lamps, and that subsequent inventions immediately copied this peculiar arrangement, it is contended on the other hand that the present suit is only brought after nearly a decade has elapsed and the contestant had failed to secure broad claims. Further, that no attempt was made to enforce the patent until a vast amount of capital had been enlisted in the manufacture of lamps by various parties, and the stakes were, therefore, enormously great. A peculiar feature of the case is the fact that the very experts who endeavoured to show the virtue of the invention in the Sawyer-Man case during the McKeesport trial, are now engaged in denying similar virtues to the Edison lamp of the same period. The complainant undoubtedly depends very greatly on the effect of Edison's name, and the general results of his work, rather than on a close interpretation of the specific claims of the patent. The defendant attacks the particular patent in suit, and also raises the claim that much of the commercial success of the incandescent lamp so strongly urged by the Edison Company was due to the system of distribution, and the production of a successful dynamo. By a curious coincidence, too, the experts who in the present case lay great stress on the importance of the lamp as a factor in commercial success, have been employed in the Edison feeder patent, and there take the position that the lamp was only a convenient concomitant of the very valuable and supremely important matter of the system of distribution. In fact, some of the experts on both sides have made a showing that is anything but creditable, and they have, in consequence, been severely scorched by the counsel. The decision will not probably be rendered before the end of the current month, and in all probability the case will be appealed to the newly constituted circuit court of appeals for final decision. The counsel for complainant appear firmly to believe that the second claim will be given a construction broad enough to cover the modern incandescent lamp, while the defendant expects that the patent will be sustained, but with such limitations as to make it practically useless. To sum the matter up, in spite of the great influence of Edison's work on the incandescent lamp, he is suing on a patent that looks somewhat shaky, in spite of its having been sustained in some foreign decisions, and the opinion in the McKeesport case, while generally upholding the Edison claims, injured them incidentally.

The Rapid Transit Question in New York.—The decision of the rapid transit commissioners has been received by the public with somewhat qualified assent. The Gould interests of this city are, of course, very strong, and there is a decided tendency to favour some extensions of the elevated railroad system, probably for the reason that a considerable addition could be made to these lines in less time than it would take the engineers of the tunnel system to get fairly settled down to their work. Nevertheless, there is little likelihood that the elevated roads will receive the commission they ask for to seize upon Broadway for an express service. A tunnel we are likely to have; and, given this, electric motive power follows as a matter of course. Incidentally, it may be mentioned that the Hudson River tunnel, now nearing completion, will probably be equipped with electric motors, and proposals have already been received from the Thomson-Houston Company for furnishing electric locomotives adequate to handle heavy trains at the highest speed desirable under the circumstances.

TRADE NOTES AND NOTICES.

This day "The Electrician" Company will publish "The Electrician" Primers (38 in all) in two volumes, price per volume 2s. paper covers, 2s. 6d. cloth; post free, 2s. 2d. and 2s. 9d. respectively. Single copies, 3d.; post free, 3½d. Prospectus on application to the Publisher.

Tenders Invited.—The Corporation of Dover invite tenders for the execution and maintenance of works needed for the supply of electricity within the borough. Copies of the conditions may be obtained of Mr. E. Wollaston Knocker, town clerk, to whom tenders must be delivered not later than Friday, July 10th. Further particulars appear in our advertisement columns.

——— The Taunton Town Council invite tenders for the supply and erection of electrical fire calls. All information may be obtained at the office of the Water Works Manager, Municipal buildings, Taunton, and tenders must reach Mr. T. Meyler, town clerk, by July 6th.

Sales by Auction.—Our advertisement columns contain announcements of the sale by auction, by Messrs. Hobson, Richards and Co. (by order of Mr. Justice Kekewich) of the plant, stock and machinery of the Electrical Engineering Corporation (Limited), at the Alliance Engineering Works, West Drayton, and No. 36, Albert Embankment. The sale at the Alliance Works is on Tuesday, June 30th, and following days, and at No. 36, Albert Embankment, on Tuesday, July 14th, and following days.

Oriental Telephone Company (Limited).—An official notification appears in our advertisement columns that a petition has been presented to the Chancery Division of the High Court of Justice for confirming a special resolution authorising certain alterations in the Company's Memorandum of Association. This petition is to be heard before Mr. Justice North, on Saturday, July 11th, when any creditor or shareholder of the Company desirous of opposing the making of an Order in compliance with the petition must attend by himself or counsel.

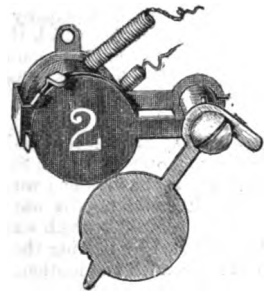
Appointment.—Mr. A. H. Hardie Trott has accepted the position of electrical engineer to the British Guiana Electric Lighting and Power Company (Limited).

Messrs. Barnett, Wynne and Barnard.—We regret to learn that the electrical department of this firm was totally destroyed by

Digitized by Google

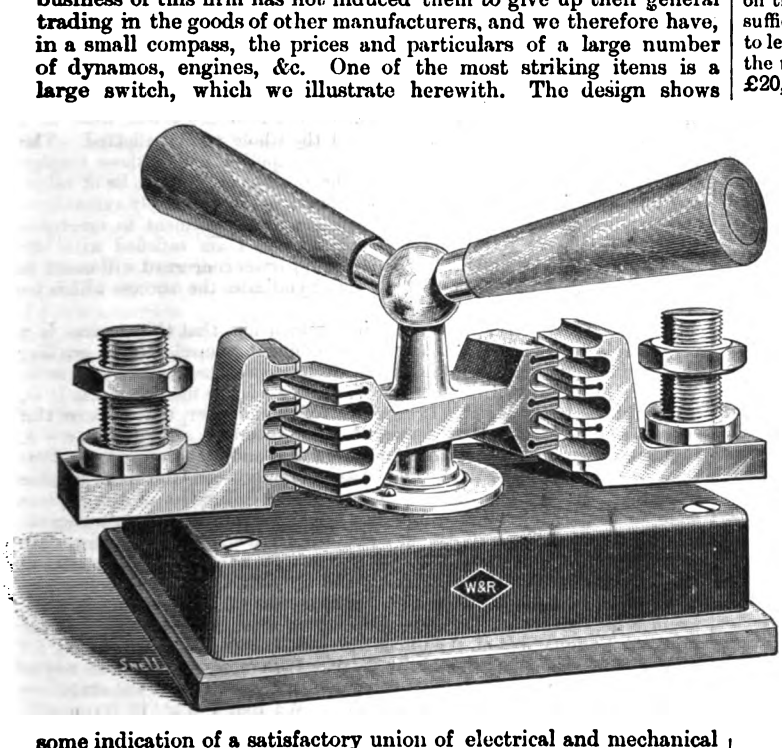
the fire which occurred at Newcastle-on-Tyne on Saturday last. All the drawings and testing instruments were lost, and the firm are suffering great inconvenience in consequence.

MR. H. THORPE.—Mr. Thorpe sends us particulars of his improved design of patent semaphore indicator, and we give a small illustration of the indicator. It has been in use for five years, and the inventor has put down new and special tools for the newly designed patent. It is claimed for the indicator as a



special advantage that when the disc is dropped there is a full white opening to show clearly and regularly which action is being used. In the printed particulars issued by Mr. Thorpe a flattering testimonial is set out from Prof. Silvanus P. Thompson in his Cantor Lecture delivered in the early part of 1890.

WOODHOUSE AND RAWSON'S CATALOGUE.—Whatever degree of finality may have been reached in the design and construction of dynamos, batteries, switches, and the innumerable goods which are known as contractors' supplies, the last new catalogue shows that the art of collating price lists knows no such limit, and the six sections which we have received of the present example excel anything of the kind that has yet been put forward. The whole catalogue will consist of eight parts, dealing with (1) boilers, engines, turbines, &c.; (2) dynamos, motors, and accumulators; (3) arc and incandescent lamps; (4) switches, switchboards, &c.; (5) fittings and shades; (6) instruments; (7) machine tools, sundries, &c. The fifth section has been surpassed, as might be expected, by some of the artistic efforts of our decorative metal workers, but, as a whole, the catalogue is particularly useful since the extended manufacturing business of this firm has not induced them to give up their general trading in the goods of other manufacturers, and we therefore have, in a small compass, the prices and particulars of a large number of dynamos, engines, &c. One of the most striking items is a large switch, which we illustrate herewith. The design shows



some indication of a satisfactory union of electrical and mechanical engineering. The independent stiff spring faces are good, since the strain on one pair need not affect the seating of the others. The small radius of the contacts and the large radius of the handles is also noteworthy. The description in the catalogue speaks of the distribution of sparking over a large number of points, but in our opinion matters should almost always be so arranged that a large current should never be broken, or, indeed, made by means of a switch. The only thing that we do not like about this pattern is the split terminals. These are good enough for temporary work, but, as we have before observed, the only workmanlike way of connecting a cable is by thimbles sweated on the end. These, we observe, are provided on the double pole two-way switch on p. 186 of the catalogue.

SANITAS COMPANY (LIMITED).—This Company, who are the manufacturers of the well known "Sanitas" specialities, have recently brought out the "Sanitas Disinfector." This should be found useful in large establishments where numbers of workmen are employed, particularly while the influenza epidemic is prevalent.

COMPANIES' MEETINGS & REPORTS.

City and South London Railway Company (Limited).

An extraordinary general meeting of this Company was held on Tuesday, at Winchester House, Old Broad-street, for the purpose of considering special resolutions for increasing the capital of the Company. Mr. C. G. Mott presided.

The CHAIRMAN explained that the shareholders would remember that the question of additional sidings at Stockwell was approved by them at the last meeting, and the question of further engine power and rolling stock was referred to in the last report; and what they had to decide upon now was the most economical method for increasing the capital for such payment. The amount they proposed to raise was about £50,000. As to the working of the concern he considered it had been most satisfactory, for all the arrangements at first had to do with the new power—electricity, for which they could not get a trained staff, but had had to educate a staff for the purpose. The men, however, had now become more efficient, and they were able to reduce the number of the staff. Another point was that the electrical engines supplied to them had not done the amount of work anticipated by the Directors. The locomotives had not been up to the power which they had expected, and they had accordingly ordered further locomotives from other makers, which they trusted would enable them to run their trains more frequently and at a greater speed. They had carried during the time that the line had been opened three millions of people in perfect safety. The question of how the additional money was to be raised had received their most careful consideration, and they had arrived at the conclusion that an issue of preference shares would probably be the best course at the present time. As to the results of the operations of the Company, he thought that under the circumstances of their being an entirely new line, they must be regarded as perfectly satisfactory. They were earning at the present moment an income at the rate of £40,000 per annum, and the whole of the working expenses, including administration charges, were estimated as near as they could get them at £28,000, which left a profit of £12,000 per annum on their present earnings. This, of course, was very small, but it was sufficient to pay their debenture interest, which was a little over £8,000, and to leave a margin of between £3,000 and £4,000 over. He hoped that during the next 12 months they would increase their receipts by from £10,000 to £20,000, and perhaps reduce their expenditure, and then they would be able to pay a moderate dividend upon the ordinary share capital of the Company. Altogether he thought the working of a new system such as theirs with such results must be regarded as satisfactory, and he concluded by moving the following resolution, explaining that the shareholders, having previously authorised the issue of ordinary new capital, must first cancel that power before they could issue preference capital:—

"*That the resolution passed at the general meeting of the Company held on August* 12, 1890, *relating to the creation of the new capital authorised by the City and South London Railway Act*, 1890, *be and the same is hereby cancelled and annulled except as to the creation and issue of* 5,000 *ordinary shares of* £10 *each, part of the total number of* 20,000 *shares authorised by the same resolution.*"

Mr. HANBURY seconded the resolution.

Mr. COURT, as representing a large number of ordinary shares, objected to the raising of preference capital, and moved an amendment for the adjournment of the meeting for 14 days for the further consideration of the matter.

Mr. MIDDLETON seconded the amendment.

Mr. PETO supported the original proposal, and expressed his satisfaction at the results already achieved by the Directors in regard to the working of the Company.

After some further discussion the CHAIRMAN expressed his willingness to accept the amendment, and it was accordingly put to the meeting and carried.

The proceedings then terminated.

Electric and General Investment Company (Limited).

The second ordinary general meeting of the shareholders of this Company was held, on Wednesday last, at Winchester House, Old Broad-street, under the presidency of the Duke of Marlborough.

The SECRETARY (Mr. J. Cecil Bull) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN said he had great pleasure in bringing before the notice of the shareholders the report which had been drawn up for their perusal, and at the same time he thought it would be a proper time to make a few supplementary remarks on the subject. In the first place,

Digitized by Google

they would see that the net profit which had been earned by the Company to May 31st was £2,592. 6s., which was to be distributed in the form of a 10 per cent. dividend, together with a bonus of 12s. 6d. per cent. on the capital paid up on the ordinary shares. It was also proposed to place £265. 10s. 9d. to reserve, to pay a dividend of £1. 5s. on each founder's share, to pay £59. 4s. 6d. additional remuneration to the Directors in accordance with the Articles of Association, and to carry forward £16. 10s. 9d. in equal moieties on account of the ordinary and founders' shares. Generally speaking, of course, this was a very poor year in the nature of things in point of business. It was the first year in which they had embarked in their enterprise, and he thought a great deal of credit was due to the persons who had taken the prime interest in its formation. The establishment of the Company was attributable to two or three gentlemen who foresaw the enormous development that was likely to take place in the electric lighting industry, which, to a large extent, had been up to the present in its infancy. The moment, however, had now come when electric lighting had reached a commercial basis. During the last 10 years it had been in a state of tentative progress—marred by many failures. But those failures had taught people the lines on which to proceed, not only with regard to improving the appliances for electric lighting, but as to the way of dealing with them commercially. Engineers were now able to give exact figures as to the cost of producing power sufficient to light a given number of lights. Given a certain area, they knew the estimates that might be made for lighting it, and they could also calculate with very great certainty the profit that would be derived from such an undertaking. They would, therefore, understand that that point having been arrived at, it was quite natural that they should look upon the question of electric lighting as having reached what he would call a commercial basis. The gentlemen who proposed to the shareholders to invest their money in this undertaking foresaw that large demands would be made for capital for carrying out various projects for lighting both the City of London and provincial towns. He might say that from the year's experience they had gained of the condition of the industry they saw promise of enormous business in all directions. Not only were private individuals engaged in forming companies for lighting towns, but municipalities were also embarking on the same enterprise; and, as they were aware, Provisional Orders had been applied for for districts and towns all over England. Those Provisional Orders would lead to the formation of companies which would have to be financed. The function of this Company was to set those enterprises on their legs, and to set them on their legs on a thoroughly conservative basis—in other words, to select those that promised well, and to reject others, which, as far as they could determine from experience, they did not think were suitable for pushing. As far as he had been able to judge from what had been brought before the Board there was great promise of development in the future. Of course the absolute business which they had done this year had not been very large, though, having regard to the amount of subscribed capital, he thought the results would be regarded as satisfactory. He hoped that in another year they would see a large increase of business. He could hardly take them into the confidence of the Board so far as the proposals before them were concerned; but there were many subjects of very great importance which they had to consider, and, of course, they must remember that the condition of the money market had not been very favourable for them. In fact it was necessary for any such company as this to proceed with very great caution. Some years ago one had only to bring out any company on the London market, and there was no difficulty in finding subscribers. He thought, however, that the present period of depression would gradually pass off; and, whatever might be said of the want of success which had attended some foreign ventures in the last few years, a good home industry would be likely to produce satisfactory results. They knew what railways and gas and water companies had done in later years. Although it would be premature to say that they had arrived at that stage when the electric light would displace gas, there was no doubt that the former would in a short time be a very serious competitor to the gas industry. He thought that in many cases, and probably in this City of London, gas as an illuminant would be supplanted altogether. Although the electric light was more expensive than gas, the former had enormous advantages over the latter, by reason of the absence of bad atmosphere where it was used, and also on account of the deteriorating effects of gas upon paintings and other decorations, which would induce householders to adopt electricity in preference to gas. He fully believed that as the facts in connection with the electric light became more known its development would be such as to surprise them. There was no doubt that the electric light companies, as far as they knew, were earning good dividends, and there was great encouragement to all those persons connected with them to develop electric lighting generally. The success of such developments must largely depend on the manner in which the schemes were taken in hand. The Directors had taken every pains to acquaint themselves with the opinions of the leading experts in this business, and to know exactly the lines on which it could be successfully conducted. In this respect the shareholders were in a much better position than some other industries, for if one were to take an electrical enterprise to one of the large trust companies in London, those companies would have to call in special advice. The Directors of the Electric and General Investment Trust, on the other hand, had spent their time in posting themselves in the electrical industry, and would therefore, he thought, be able to judge what kind of business to foster and what to reject in the interests of the Company. He thought they would be satisfied with the small results obtained this year, and he hoped it would be his fortune to make a further statement 12 months hence, which would be a great improvement on that which he had just made. He moved

"*That the report and statement of accounts to May* 31, 1891, *be and are hereby received and adopted.*"

Mr. GEORGE HERRING, in seconding the motion, said that, if they would look at the accounts, they would find loans against consols £10,000, and cash on deposit £10,000—that was to say, the money was intact, and they could have if they liked £20,000 back in 24 hours. The business of the Company was, to a certain extent, to promote and encourage electrical undertakings, and the Directors had been very careful indeed in choosing only those which they thought of great importance. One which he might as well mention was the lighting of the City of London. The three districts had been amalgamated into one, and would be lighted by one Company, which would be brought out very shortly. The reason he mentioned this was that the shareholders in this Company would have a priority of claim in any allotment of its shares for which there would, he feared, be many applications. But if the shareholders would mention on their forms the fact that they were shareholders in this Company, the Directors would see that priority would be given to them.

The motion was carried unanimously.

Mr. KELMAN asked when the dividends would be paid, and when there was a probability of getting a quotation on the Stock Exchange.

The CHAIRMAN replied that the dividend would be paid immediately, and as to the quotation, it could not be obtained until they had a paid-up capital of more than £50,000, which was the minimum that received a quotation. He concluded by moving the dividends recommended.

Mr. B. H. VAN TROMP seconded the motion, which was carried unanimously.

On the motion of Mr. KELMAN, seconded by a SHAREHOLDER, the auditors, Messrs. Rail and Kearton, were re appointed, and, a vote of thanks having been accorded to the Chairman, the proceedings terminated.

Caustic Soda Syndicate (Limited).

The statutory general meeting of the Caustic Soda and Chlorine Syndicate (Limited) was held at Winchester House, Old Broad-street, E.C., on Friday last; Major Burnaby presiding.

The SECRETARY (Mr. Charles O. Greenwell) having read the notice convening the meeting, the CHAIRMAN said: You are all well aware that this is merely the statutory meeting which, in conformity with the Companies' Acts, must be held within four months of the registration of the company. Those who framed this Act, enforcing a meeting at such an early date, could have had little idea of the difficulties arising from the manufacture and the placing of the necessary machinery to enable us to demonstrate satisfactorily the process, which is, in itself, novel and original. It was the desire of the Board to inform you that we have absolutely manufactured caustic soda and chlorine by Mr. Greenwood's process, which is now being erected at our works in Battersea. We hope at a very early date to be in a position to ask you to meet us at the works to witness a full demonstration of this very valuable process. There appears to be little or no doubt as regards the result. Mr. Greenwood is now more than ever assured of the success of his invention, which, I need not mention, is undoubtedly one of the most important of the day. The shares offered to the public were in a short space of time over-applied for, and the whole capital allotted. The Directors have caused the patents to be applied for in those foreign countries and the colonies wherever the process is likely to be of value, and when obtained they will, no doubt, prove to be extremely valuable to this Syndicate. Although it is some little disappointment to meet you without absolutely having proved our success, I am satisfied with the working up till now, and I fully believe all parties concerned will assist in the one common object of making this Syndicate the success which we believe it will shortly prove to be.

Mr. GREENWOOD: I may say, in commencing, that this process is a very simple one; in fact, Mr. Ashton, the eminent counsel, said, in settling the specification, that it is one of the simplest processes he had ever seen. You are aware that the more simple a process is the more valuable it is, other things being equal. It does not follow, however, that because the process is simple it is easily worked. The reverse is often the case. A simple process usually requires more careful and elaborate preparation than other processes, and that has certainly been the case in this instance. I may say that all the scientific difficulties of the process were, of course, overcome before this Syndicate was formed. As regards the success of the process, it was amply demonstrated before we called upon you to subscribe one penny. It was, however, one thing to overcome the scientific difficulties, and another thing to overcome the engineering difficulties. The last three months we have overcome these engineering difficulties, and, I am glad to say, most successfully. Let me give you a fair sample of the difficulties which have caused this delay; I do not think, though, I should say delay. I do not suppose that any of you ever heard of a new process being demonstrated before the statutory meeting was held. I never knew of one. We found that, in connection with our anodes, greater delay had arisen in the progress of electrolysis than in any other thing. I claim that we have at last produced an anode, at a small expense, which is unique of its kind, and which places this Company in a position to beat any rivals, and I have no fear as regards any rivalry. After placing out our anodes to be made according to specification with two or three firms, they were returned to us, after trying their best to make them, in an altogether unsuitable condition, and we were actually obliged to take the making up of them ourselves. I myself put down the existing plant, and I invented apparatus to make these anodes, and, further than that, I introduced an improvement which I have patented only this week, which makes these anodes ten times more durable than any carbon anodes that have hitherto been made. And, therefore, the value of your patents now is considerably more than it was three months ago. Another feature in connection with this is the Diaphragm. The two main points of this process are the anode—which, I think, we have brought almost to

Digitized by Google

perfection—and the Diaphragm. This Diaphragm has given us little or no trouble. I expected to have the most difficulty and most trouble with the Diaphragm, but it has turned out that we have had practically no trouble whatever with it. I consider it to be as perfect as it is possible to make it. The principle of its construction is based on a well-known pneumatic law. We know that all sorts of things have been done by electrolysis, with a view to the separation of the products electrolysed, and this process has been employed by every scientific inventor for the last 40 or 50 years. I claim that we have introduced a Diaphragm which, for its efficiency and cheapness, and for quality to render it serviceable, is unique of its kind, and altogether in advance of anything that has been done before. And as regards the details of the process, I am sure that when the shareholders meet us—which I hope they will do in the course of a month—they will not only be pleased, but will be astonished at such remarkable results being achieved by such simple means, for the whole thing is based upon very simple methods. We have achieved results that have exceeded my expectations, and I can only say that you have a very valuable property, and that if I were a rich man I should not mind buying every shareholder out myself.

A SHAREHOLDER, in proposing a vote of thanks to the Chairman, expressed his gratification at what he had heard, and felt confident as to the ultimate success of the undertaking.

The motion, having been seconded, was carried, and the CHAIRMAN having briefly replied, the proceedings terminated.

House-to-House Electric Light Supply Company (Limited).

The following is the second annual report of this Company's operations, being for the year ended December 31st last, to be presented to the third ordinary general meeting to be held at the Company's Central Station, Richmond-road, London, S.W., this day (Friday), at 3 p.m. :—

1. The Directors have pleasure in submitting to the shareholders (in the form now prescribed by the Board of Trade) balance-sheet and profit and loss account showing the operations of the Company from January 1st to December 31st, 1890.

2. After placing to capital account the debenture interest and loss on working to September 30, 1890, up to which date the business was being established, the net revenue account shows a credit balance of £385. 15s. 8d., which is carried forward to the next accounts.

3. The period under review has been mainly spent in building up the Company's business; the number of lights attached to the Company's circuit on January 1st being 4,520, and the number on December 31st being 13,665, pointing to the probability of good returns in future years.

4. In this connection the following statement is interesting :—

Date.	Working expenses.	Revenue.
January to June, 1890...	£1,921 0s. 7d.	... £1,373 6s. 7d.
July to December, 1890..	2,703 5s. 10d.	... 3,637 2s. 7d.

5. At the beginning of the year there were 78 houses connected to the Company's circuits, and on December 31st there were 248 houses.

The number of connected lamps, as already stated, on December 31st was 13,665, which has since been increased to 16,144 in 304 houses, whilst fully 4,000 more lights are wired or are in process of wiring.

6. The Company's mains, extending to nearly nine miles, are now laid in the following roads, &c. :—

Allan-terrace	Earl's Court-road	Nevern-square
Ashburn-place	Earl's Court-square	Newland-place
Astwood-road	Evelyn-gardens	Newland-terrace
Barkston-gardens	Fopstone-road	Old Brompton-road
Barkston-mansions	Foulis-terrace	Onslow-gardens
Bath-place	Fulham-road	Onslow-square
Bina-gardens	Gilston-road	Pembroke-gardens
The Boltons	Gledhow-gardens	Philbeach-gardens
Bolton-gardens West	Gledhow-terrace	Priory-gardens
Bramham-gardens	Gloucester-mansions	Queen's-gate
Bramham-mansions	Gloucester-road	Redcliffe-gardens
Clareville-grove	Gloucester-terrace	Redcliffe-square
Claro-terrace	Harcourt-terrace	Richmond-road
Colherne-mansions	Harrington-gardens	Roland-houses
Colherne-road	Harrington-road	Roland-gardens
Colherne-terrace	Hereford-square	Rosary-gardens
Collingham-gardens	Hogarth-road	Somerset-terrace
Collingham-place	Kempsford-gardens	Stanhope-gardens
Collingham-road	Kensington-road	Sumner-place
Courtfield gardens	Kensington-mansions	Sussex-place,
Courtfield-road	Knaresborough-place	Trebovir-road
Cranley-gardens	Lexham-gardens	Tregunter-road
Cranley-place	Marloes-road	Warwick-road
Cromwell-mansions	Moreton-gardens	Wetherby-gardens
Cromwell-road	Nevern-mansions	Wetherby-road
Drayton-gardens	Nevern-road	York-mansions

7. With a view of providing capital for the extension of the Company's business in Kensington, and in order to keep pace with the demand for the light, an issue of Seven per Cent. Cumulative Preference Shares was sanctioned in December last by the shareholders. The depressed state of the Money Market having interfered with the subscription of capital, the Directors will be glad if the shareholders will personally interest themselves in this issue and subscribe the necessary amount to admit of the extension of the Kensington station; a step which is necessary in order to comply with the obligations of the Company's Provisional Order, and to secure a satisfactory return upon the capital already invested.

8. The Directors are considering proposals for vesting the Company's interests outside the Metropolitan area in a construction company, and it is hoped that a steady annual addition to the profits of the Company will accrue from this source.

9. During the year, Mr. F. J. Burt and Mr. C. T. D. Crews resigned their seats at the Board, and the vacancies were filled up by the election of Mr. W. Page and Mr. R. A. Germaine, who are the retiring Directors, and, being eligible, offer themselves for re-election.

10. At the meeting, the shareholders will have to elect auditors for the ensuing year; Messrs. Theobald, Bros., and Miall, being eligible, offer themselves for re-election.

NEW COMPANIES REGISTERED.

ANDOVER GAS AND COKE COMPANY (LIMITED).—Registered by Waterlow Brothers and Layton (Limited), Birchin-lane, E.C., with a capital of £8,000, in £10 shares. Object: to carry on at Andover, Hants, the business of a gas company in all its branches, and also to carry on generally the business of an electric light and power company.

KINGHORN GAS LIGHT COMPANY (LIMITED).—Registered in Scotland by James Inglis, solicitor, Edinburgh. Capital, £1,200, in £1 shares. Object: to carry on the distillation of coal, oil, or other substances, so as to procure inflammable air or gas or other substances for illumination, heating, and other purposes of the town of Kinghorn, Fifeshire, and suburbs, or such parts thereof as may be deemed expedient; to supply electricity there; to sell gas and electricity, and the coke, tar, and other products arising from the distillation of coal, oil, and other substances, and to manufacture such products into articles of commerce.

OGMORE VALLEY ELECTRIC LIGHT AND POWER SUPPLY COMPANY (LIMITED).—Registered by Jordan and Sons, 120, Chancery-lane, W.C., with a capital of £10,000, in £5 shares. Object: the carrying on in the Ogmore Valley, and elsewhere in the county of Glamorgan, the business of an electric light company in all its branches.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the past week amounted to £5,670.

CALEDONIAN TELEPHONE COMPANY, LIMITED.—A prospectus of this Company has been issued. The Company has been registered with a capital of £50,000, divided into 50,000 shares of £1 each, with power to increase. The present issue is for 10,000 shares of £1 each, payable 5s. on application, 5s. on allotment; balance not arranged for in prospectus. The interim secretary is Mr. William Barton, of 109, St. Vincent-street, Glasgow. The Company has been formed to acquire from Mr. A. Erskine Muirhead, of Cart Forge, Crossmyloof, and 109, Hope-street, Glasgow, the business carried on by him of supplying telephonic communication among traders generally, and more especially of connecting branch offices and departments with the head offices in connection with collieries, railway companies, iron founders, mill owners, public works, &c. The prospectus states that the Company commences business free from all patent duties, royalties, or other heavy charges against capital. The objects of this Company at the outset will be :—(1) To take over and thereafter develop the business commenced by the vendor of supplying private wires between central offices and their branches, and connecting different departments of works; (2) To enter into contracts for the maintenance of private wires; (3) To establish telephone exchange communication in towns; (4) To carry on the business of buying and selling telephones. The instrument used by the vendor is the French telephone, as made by The Société Général des Téléphones, and which is capable (the prospectus further states) of speaking a distance of over 500 miles. The stock, plant, and effects of the vendor will so far as necessary for the Company's business be taken over at a valuation. No price has been paid for goodwill. The vendor is in negotiation with a large number of firms for telephonic communication, and those contracts will be taken over by the Company. *While personally fully satisfied with the statements and estimates contained in the Prospectus, the directors do not in any way warrant them.* Prospectuses can be had of the secretary.

CITY AND SOUTH LONDON RAILWAY COMPANY.—The traffic receipts of this Company for the past week amounted to £860. The aggregate receipts for the half-year to date are £17,779.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—Notice is given that the coupon on this Company's Five per Cent. Australian Government Subsidy Debentures, due on July 1st prox., will be paid on and after that date at Messrs. Barclay, Bevan, and Co., 54, Lombard-street, E.C. Coupons must be left three clear days for examination.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended June 12, 1891, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,027.

NEW VALVE

No Rubber, Percha, or Leather.

One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept. 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to MOSSES & MITCHELL, 68-71, Chiswell Street, London.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 684.—Vol. XXVII. FRIDAY, JUNE 26, 1891. Price Fourpence.

NOTES.

The Central London Railway scheme was thrown out last year owing to an opposition of a very varied description. Amongst other alarms it was urged that mischief would be wrought on the foundations of St. Paul's, and that the dome would be in grievous jeopardy. This year the Dean and Chapter of St. Paul's were, we believe, propitiated by an alteration in the proposed site of the Cheapside station, and in consequence of this and many other similar concessions, the preamble has been proved. We can only hope that the passage of the Bill will now meet with no further impediment. It has been suggested that the direct competition of this line may cause the omnibus routes to be diverted through the less important thoroughfares, and that the streets immediately above the railway will be thus relieved. The recent strike has shown Londoners what a boon such a relief would be, and the short experience which they have recently enjoyed has probably told strongly in favour of the Central London Railway.

The outcome of a meeting which was held some two months ago to express dissatisfaction with the present telephone service in London was, as we reported at the time, the formation of an Association for the Protection of Telephone Subscribers. A circular has now been issued from the offices of the London Chamber of Commerce, in which it is stated that the Committee confidently feel that great benefits can be obtained by united action, and that it is only by combination that increased efficiency and a reduction in rental can be attained. Unless well backed up by the Post Office, it is difficult to see how this body intends to act with effect. The lapse of the telephone patents will hardly affect the London service of the National Telephone Company to the slightest degree; the property which they own, and the position which they have acquired, has long since ceased to consist in any monopoly of instruments, but in the system of wires and exchanges by which any one individual, if he has the necessary patience, may be put in connection with any other of the 6,419 subscribers. The "inefficiency" of the service presumably refers to the many inconveniences, such as delay in "getting through," "cross-talk," and the maddening "ticker," but constant improvements are being made, and the Company is always ready to investigate complaints, and frequently succeeds in removing the trouble. We are aware that many important houses of business decline to avail themselves of the present telephone service on account of such defects, and shrink from risk of verbal misunderstandings. Our Copenhagen correspondent justly boasts, in another column, of the wonderful service in Stockholm, which, already having the largest number of telephones per hundred inhabitants, proposes an annual subscription of 11s. per annum, and a fee of 1½d. for each message sent. But we can never expect that this figure will ever be approached in London, if only on account of the price of labour and way-leaves.

Of the many muddles which municipal authorities have made in dealing with the question of electric light, none has been so complete as that in which the Cambridge Town Council has floundered In the first place, Dr. Fleming was asked for advice, the next step was to invite tenders in accordance with his general recommendations for a transformer system of distribution, no elaborate specification being given, but a free hand being allowed to each firm to recommend what it thought best. Certain tenders were recommended, and a local architect furnished plans and an estimate for a building, based upon the requirements of the contractors, his estimate being £4,900. Tenders for the erection were invited from local builders, and the lowest was found to be £11,260. Thereupon it was decided to abandon the whole scheme.

A committee of the Town Council, imagining that if they actually saw the wheels go round they would learn more than any consulting engineer could teach them, started off on one of those tours in which such gentlemen delight. We have read their report, but fail altogether to understand why they approved so highly of the Parsons steam turbine; possibly the wheels went round at a more surprising speed than elsewhere. Mr. Parsons estimated the building and equipping of a suitable station at £13,500. Dr. Fleming could not recommend this ingenious motor (which doubtless is excellently adapted for certain purposes) as an economical steam engine possibly because no satisfactory information on this point has as yet been published. But a different opinion is held by Prof. Garnett, who takes a kindly interest in the Parsons engine, since it is used at Newcastle by the local supply company with which he is connected. Dr. Porter sensibly suggested that Prof. Kennedy should be referred to, to decide the question, and outside the ranks of engine builders, no better man than Prof. Kennedy could be selected. But the committee have decided to proceed with the muddle which they call their scheme, at a cost not exceeding £26,500, and to engage Prof. Garnett as consulting engineer.

In the current number of the *Electrical World* of New York appears a preliminary statement in connection with a new alternate current motor system due to the joint efforts of Mr. William Stanley, jun., and Mr. J. F. Kelly. The authors propose to overcome the difficulties encountered in working alternate current motors, owing to the self-induction possessed by the armature and field magnet circuits, by the device of using condensers of suitable capacity in shunt or series with the coils. They claim to have so far succeeded in the application of this idea that they can supply alternating currents to the ordinary type of motor, possessing great self-induction, and develop the field magnetisation in the same manner as though the motor were supplied with direct currents of constant value. The practical details of the work which these engineers have actually carried out will, no doubt, prove of great interest as soon as it is published, but the present communication contains very little information that is really novel. The authors acknowledge that the possibility of annulling self-induction by capacity has been previously pointed out, and state that the theoretical portion of their work was completed before the publication of the discussion on the Ferranti effect which has recently taken place in our columns and elsewhere. But the idea is well known, not only to theorists but to practicians, for it has already received important applications in telegraphy. The writers suggest that the troublesome currents in telephone lines, due to induction and leakage from neighbouring electric light and power circuits, might be suppressed by inserting a condenser in the line. A condenser transmits a current more readily as the frequency of the alternations is increased, and thus may act as a conductor for the rapid telephone currents, and as an insulator for the slower currents due to the various disturbing influences. This device is, however, essentially the same as that often employed on combined telegraph and telephone lines.

Much has been written at various times about the mathematical peculiarities of combinations of coils and condensers, but before they can be turned to practical account many difficulties have to be surmounted. One of the greatest of these is the production of suitable condensers at a reasonable cost. Another arises from the fact that the self-induction of all iron cored cir cuits varies considerably with the current, so that any method dependent upon the adjustment of a condenser to neutralise self-induction must be so arranged that the capacity of the condenser used can be altered when necessary. A third difficulty arises from the necessity of increased insulation. The voltage required to produce a given current in an inductive coil is dependent merely upon the coil itself; it cannot be altered by any external arrangement of condensers. It is true that by means of the latter a larger current can be produced in the coil by a given voltage supplied by the leads, but this can only be from a resonance effect in consequence of which the voltage on the coils rises to a greater value than that supplied by the distributing mains.

Society of Arts.—The Council of the Society of Arts have awarded a silver medal to Prof. William Robinson for his Paper on "The Use of Petroleum in Prime Motors."

Postal Appointment.—Mr. J. J. Towers, sorting clerk and telegraphist, of Kirby Lonsdale, has been appointed Postmaster of Cockermouth.

Tangier.—The Spanish "Compañia Transatlantica" have decided to introduce the electric light into Tangier, and the material for this purpose is expected to arrive very shortly.

Erratum.—In the article on "Magnetism in Iron and other Metals," No. XLIII. (*The Electrician*, June 19th, page 182), in the second last line: for "40π" read "$0{\cdot}4\pi$," and for "125·66" read "1·2566."

Reminiscences of Faraday.—"Dagonet," in the *Referee* of the 21st inst., relates some extremely interesting personal reminiscences of Faraday and his connection with the Sandemanians.

Proposed Electric Railway at Blankenburg.—It is proposed to run an electric railway between Blankenburg and Thale, the current for the purpose being supplied by the Blankenburg Electricity Supply Company.

Electric Transmission of Power Project.—A project is on foot for supplying power transmitted by electricity from the Argen, near Laimrau, to Limnau, Ravensburg, Weisenau, Tettrang, Meckenbeuren, and Weingarten.

Appointment.—Mr. J. T. Nicolson, B.Sc. (Edin.), at present Professor Ewing's Demonstrator in the University of Cambridge, has been appointed to the Chair of Mechanical Engineering in the McGill University, Montreal, Canada.

African Direct Telegraph Company (Limited).—Notice is given in our advertisement columns that the coupons on this Company's Four per Cent. Mortgage debentures to bearer, due July 1st next, will be paid on and after that date, at the Alliance Bank, Bartholomew-lane, London, E.C.

Electric Traction in Paris.—La Société des Tramways de Paris et du Département de la Seine are about to start a regular service of electric cars from the Rue Lafayette, near the Opera, to St. Denis, over a line having some very steep gradients. The electrical rolling stock will consist of 20 fifty-four passenger cars.

Atlantic Cable Competition.—As an instance of the extreme competition amongst the Atlantic companies for the telegraph traffic, it may be mentioned that the Direct United States Cable Company have issued a specially designed card message form, for use on board the Atlantic liners, to be filled up by those who wish to cable, and then handed to the purser on arrival at Liverpool, or to their attendant, whose photograph appears on the back of the card.

Cambridge.—The Town Council were engaged for a considerable time on Tuesday last week in discussing the report of their Electric Lighting Committee, and ultimately decided to accept the recommendation to adopt Mr. Parsons's system, and further authorised the committee to conclude contracts for carrying out the electric lighting of the town, at a cost not exceeding £26,500, on the understanding that the installation should suffice for 10,000 lights of 8-c.p., or their equivalent. Prof. Garnett, of Newcastle, was also appointed consulting engineer.

An Electric Light Installation for the Greenwich Observatory.—In view of the advantage resulting from the use of electric lighting for the photographic, equatorial, and for other instruments, the Astronomer-Royal considers it very desirable that an electric light installation should be provided for the Greenwich Observatory, so that this method of lighting, which is specially adapted to the requirements of an observatory, may be applied to the instruments generally. The system now in use is that of charging storage cells from primary batteries.

Automatic and Multiplex Telegraphy.—Mr. Gisborne recently read an interesting Paper on the above subject before the third section of the Royal Society of Canada. Mr. Gisborne is reported to have stated that 3,000 words per minute had been transmitted by a copper wire line, 355 miles in length, between New York and Washington, and 800 words over a similar wire 1,000 miles in length, between New York and

Digitized by Google

Chicago, and that 600 words per minute have been transmitted by repeaters beyond that distance.

The Lighting of the City.—At the last meeting of the Commissioners of Sewers the report of the Streets Committee was presented, which contained a reference to the proposed transfer of the undertakings in regard to the City electric lighting to a new company, to be formed under the title of "The City of London Electric Lighting Company." The Committee recommended that this transfer should take place providing the Commissioners were satisfied with the particulars. After some discussion, and the proposal of a couple of amendments, the report was adopted.

Obituary.—William Edward Weber, the eminent German physicist and the co-worker of Gauss, died at Göttingen on Wednesday at the age of 86. We hope next week to give a full obituary notice of this great worker in the electrical field.—The death is announced of Prof. L. V. Lorenz, of Copenhgen, well known for his electrical work. In 1882 Prof. Lorenz represented Denmark on the International Committee which met in Paris to fix the electrical units. He was also the author of several standard works on light and heat. The Lorenz and Jürgensen dynamo was awarded a gold medal at the Paris Electrical Exhibition. Prof. Lorenz was in his sixty-third year.

The British Association.—A large and influential meeting was held at Edinburgh, last week, to consider the arrangements which ought to be made for the visit of the British Association to that city next year. The Lord Provost presided. A local executive committee was chosen, and Mr. A. Gilles Smith was appointed honorary local treasurer. In a letter from Mr. Griffiths, secretary of the Association, it was stated that Sir Archibald Geikie, who will preside over the Edinburgh meeting, was in favour of the meeting being held early in August. A considerable majority, however, voted in support of a proposal that the meeting should begin on Wednesday, September 28th.

Municipal and County Engineers' Association.—The annual meeting of the Incorporated Association of Municipal and County Engineers commenced yesterday. To-day Mr. W. H. Preece will deliver an address "On the Relative Merit and Cost of Gas and Electricity for Lighting Purposes;" and this will be followed by a Paper from Prof. H. Robinson, entitled "Electric Lighting by Municipal Authorities." Several visits of inspection to various works will occupy the attention of the members in the afternoon; and the whole of Saturday will be similarly employed. Among other places to be visited that day will be the works of the London Electric Supply Corporation at Deptford.

Carlow.—The town of Carlow was successfully lighted up by Messrs. J. E. H. Gordon and Co. at an early hour yesterday morning. The electricity is generated by water-power situated at Milford, five miles distant, and is conveyed to the town by overhead wires at 2,500 volts pressure. Transformers fixed on the posts in the town reduce the pressure to 50 volts, and deliver the electricity to a system of bare copper low-tension mains carried on the same posts. The arc and incandescent lamps are both attached to this. The low-tension mains extend through four and three-quarter miles of streets, and the plant is sufficient for the whole public and private lighting of the town. The work was commenced in December last.

Damage by Lightning.—On the 3rd June, a thunderstorm of great violence broke over Vienna shortly before noon and lasted for more than three hours. Some 26 houses in different parts of the city were struck. A woman and two children were killed, and many persons received injuries.—On Monday evening last, a heavy thunderstorm burst over Gloucester. The lightning struck the vane of St. Nicholas' Church, one of the oldest in the city, and set fire to the top of the roof.—According to a Reuter's telegram from Budapest, eighteen field labourers, overtaken by a thunderstorm in the Oedenburg district, sought shelter by the side of a hayrick, which was immediately afterwards struck by lightning. Three of the men were killed on the spot, and the others were stunned.

Foreign Telegrams.—The Postmaster-General has issued the following notice:—"On and from the 1st of July the rates for telegrams to many countries will be reduced, as arranged at the International Conference held in Paris. Examples:—Austria, from 4½d. to 3d. a word; Hungary, from 4½d. to 3d.; Gibraltar, from 5½d. to 4½d.; Italy, from 4½d. to 3d.; Malta, from 7d. to 6d.; Sweden, from 5d to 4d.; Norway, from 4d. to 3½d.; Russia, from 6½d. to 5½d.; Portugal, from 5½d. to 4½d.; Spain, from 4½d. to 4d.; Switzerland, from 3½d. to 3d.; Canary Islands, from 1s. 7½d. to 10d.; Java, from 6s. 10d. to 6s.; Singapore, from 6s. 5d. to 5s. 9d.; Penang, from 5s. 7d. to 5s.; Senegal, from 2s. 10½d. to 1s. 6d.; St. Paul de Loanda, from 9s. to 8s. 7d. At the same time the fees for signalling ships at foreign semaphore stations will be reduced from 1s. 8d. to 10d."

Mutual Telephone Company.—The number of subscribers on this Company's Manchester exchange actually speaking on June 19th was 366. They are being added to daily at the rate of 25 per week. The progress made might be quicker, but it is not desired to have more than 500 talking on July 30th, as after that date the magneto transmitters now being put in are to be replaced by carbon ones. We understand that the Mutual Company will be prepared on July 31st with a sensitive and efficient transmitter, made in accordance with one of the designs figured in Edison's tension-regulator patent, which expires on July 30th. Arrangements are being made to join up 50 subscribers per week after the change of transmitters has been effected, and erect trunk lines to, and open exchanges in, Bolton, Oldham, and many of the other Lancashire towns.

St. Pancras Vestry.—At the last meeting of this vestry the Electrical Committee reported that they had been endeavouring to obtain suitable premises for the sub-station required between the works and the extreme northern limit of supply. The engineer had submitted a plan for constructing a chamber for the purpose under the roadway of High-street, south of the Cobden statue. The space to be taken would be 30ft. by 16ft. The roadway to be repaved with the same sets that the Committee found there. The proposition was carried. It was also decided to issue advertisements for a competent engineer and electrician of general business experience as general manager, at a commencing salary of £250 per annum. Candidates to be between 25 and 45 years of age, and be subject to the usual conditions of the Vestry regarding appointments.

Telephone Licences.—Dr. Cameron asked the Postmaster-General, on Friday evening last, whether the patents for the more important telephones in use in this country expired in July next; and, if so, whether he was now in a position to announce the decision of the Post Office as to granting licences for telephone exchanges to applicants proposing to introduce loud-speaking and other improved forms of the telephone. Mr. Raikes, in reply, stated that it was the fact that one of the more important telephone patents expired in July. The question of the relations of the Post Office to the telephones was, he said, one of great complexity, as well as of great importance. It was more than a departmental question. The subject had been occupying the anxious attention of Her Majesty's Government, but they had not come to any final arrangement as to the course to be pursued.

The Electrical Equipment of S.S. "Scot."—The extent to which electric lighting is carried out, not only on the huge Atlantic liners, but on board all modern mail steamers, is well illustrated by the electrical equipment of the Union Company's fine twin-screw steamer "Scot" (6,850 tons), built by Denny Bros., of Dumbarton, for the South African mail service. The electric light installation consists of 650 16 c.-p. incandescent lamps, with special fittings made by Messrs. M'Geoch, of Birmingham, and four King-Brown four-pole 200 ampere dynamos. The main and auxiliary switchboards were made by Denny Bros. The measuring instruments have been supplied by Siemens Bros. In addition to the electric lighting installation a number of electric fans have been put up, and the Blackman Ventilating Company also supply several large fans for the ventilation of the engine rooms.

Berlin Electric Lighting Statistics.—The *Elektrotechnische Rundschav* gives the following particulars as to electric light in Berlin. Leipzigerstrasse is lighted by means of 36 arc lamps, which burn until midnight. In the Unter den Linden, Opernplatz, Lustgarten, and Kaiser Wilhelmplatz are 108 more arcs,

Digitized by Google

of which 60 burn the whole night, whilst 48 are extinguished at 12 o'clock. Twelve arcs serve to light the Schillingsbrücke and a part of the Stralauerplatz. The total number of arcs utilised for public lighting is consequently 156. At the end of March, 1890, 4,944 arcs and 80,788 glow-lamps were being run in Berlin. Of these the Berliner Elektricitatswerke were supplying from their central station 1,832 private arcs and 43,215 incandescents. The remaining 3,112 arcs and 37,573 incandescents were supplied from 262 isolated plants, 171 of which were driven by steam and 91 by gas.

The Germain Magneto-Telephonic Transmitter.—In a note in the *Comptes Rendus* of June 8th, M. P. Germain says "The mouthpiece of a magneto-telephone transmitter may be divided into a number of smaller mouthpieces, each corresponding to a distinct telephone armature above the opening of the air chamber. The emission of a single voice thus gives rise in all the columns of air, and on all the telephone armatures, to pressures proportional to the total surface of the armatures actuated. Each armature of the Bell electro-magnet, of which it is a part, thus develops similar, if not equal, induced currents in all the distinct and equal circuits composing the transmitter. If we connect the negative end of the first coil to the positive end of the second, and the negative end of the second to the positive end of the third, and so on to the end, and if we arrange all these circuits in series in a telephone line, it is possible to telephone to great distances without a microphone, without a constant battery, and without an Edison coil."

A Sensitive Electrical Alarm.—At the last meeting of the Académie des Sciences, MM. G. and L. Richard described an electrical alarm devised by them for the purpose of responding to variations in the pressure of a current of air or gas. The alarm is extremely sensitive, and will act for variations of a few hundredths of a millimetre of water. The apparatus consists of a metallic box communicating with the flue, through which the gas is flowing, by a small tube. This tube is closed inside the box by a light metal valve, the movements of which open and close an electric alarm circuit. By altering the position of the box with regard to the vertical, the sensitiveness of the apparatus is more or less modified, and beyond a certain point the apparatus may be made to indicate an increase of pressure. MM. Richard propose to fix this device to ventilating tubes or to flues. In some cases it may be necessary to have an additional automatic device to prevent purely momentary depressions from affecting the instrument. Where required the alarm circuit could be made to include an electro-magnet which should attract a bar of soft iron actuating a train of clock wheels, which, when a certain definite time had elapsed, should allow the alarm to ring.

The Dielectric Properties of Mica at High Temperatures.—In a Paper recently read before the Académie des Sciences, M. E. Bouty described some investigations carried out by him with regard to the dielectric properties of mica at high temperatures. The result of M. Bouty's researches is to demonstrate the almost complete invariability of the dielectric constant of mica, which, between 0° and 300°C., certainly does not alter by one-fiftieth of its original value. Above 300°C. experimental complications occur, and tend to obscure the result. M. Bouty made use of silvered sheets of mica, and when the temperature was carried beyond 300°C., the silver was attacked if in contact with the air, and the mica was soon covered by a transparent electrolytic film. This defect may be minimised by covering the silver with a fairly thick layer of copper. Above 300°C. the charge furnished by the battery is no longer entirely recoverable, which is doubtless due to the formation of the conducting film, since the conductivity at the same temperature rapidly increases if the application of the heat is prolonged, and the conductivity is maintained on cooling until the superficial hygrometric layer has been washed away in alcohol. It is possible that between 300° and 400°C. mica may possess some slight specific conductivity. However that may be, says M. Bouty, the resultant conductivity between 300° and 400°C. is negligible for charges of brief duration.

Polytechnic Institute in Chelsea.—The movement for the establishment of a Polytechnic Institute for South-West London, north of the Thames (including the districts of Fulham, Chelsea, St. George's, Hanover-square, Kensington, and Westminster), commenced in 1888. The Charity Commissioners promised to devote £50,000 to the endowment and support, on condition that a like sum of £50,000 should be contributed for its site, building, and equipment. A site in Manresa-road, Chelsea, was given by Earl Cadogan, and approved by the Charity Commissioners as convenient for the district. The value of this site is estimated at £10,000; and the amount to be raised by subscription was thus reduced to £40,000. Up to the present time the efforts of the Committee towards the raising of the required £50,000 have resulted in a total of £32,000, including the value of the site before mentioned. The plans recently selected include accommodation for—1. Technical and commercial schools and science and art classes for young men and women above 15 years old. 2. Gymnasium, swimming bath, lecture and reading rooms, music, and various forms of recreation. 3. Day schools and evening classes for boys and girls between 13 and 15 on leaving the elementary schools. Only a technical library is included, as the new buildings of the Chelsea free libraries adjoin the proposed Institute, and will be utilised by its members.

Electric Traction and the Telephone.—On June 2nd the Supreme Court of Ohio gave judgment in the case of the Cincinnati Incline Plane Railroad Company *v.* the City and Suburban Telegraph Company. This action has excited considerable attention in the United States, involving, as it does, the two great interests of telephone exchanges and electric street railways. The action was brought by the telegraph or telephone company to restrain the Incline Plane Railroad Company from constructing and running their electric railway by the use of the Sprague—single trolley system—on the plea that the "earth return" interfered with the use of the telephone, and almost destroyed their business. The Telephone Company claimed the first right to the earth, with the use of it for their return circuit. The matter could be remedied by one of two ways. First, by the railway putting in what is known as the double trolley system, by the use of which the telephone would not be interfered with. Second, by the Telephone Company, instead of using the earth for the return circuit, putting in "metallic circuits." The Supreme Court upheld the theory that the street was primarily intended for the use of the general public for the purpose of travelling and transporting goods, and the fact of motive power, which facilitates the object, being changed to something which might interfere with a subordinate use of the highway, ought not to make any difference in that regard.

The Electrolysis of Sulphuric Acid.—A further communication upon the new peroxide of sulphur, SO_4, by Prof. Traube, of Breslau, will, says *Nature*, be found in the current number of the *Berichte*. This interesting substance is obtained when solutions of sulphuric acid containing at least 40 per cent. of acid are subjected to electrolysis, as a crystalline deposit upon the anode. The crystals were first observed some time ago by Berthelot, but were considered by him as identical with the oxide S_2O_7, which he had previously obtained by the action of the silent electrical discharge upon a mixture of sulphur dioxide and oxygen. Prof. Traube, however, finds that the substance obtained at the anode in the electrolysis of 40 per cent. solutions of sulphuric acid is represented by the formula SO_4, and is quite a different substance from Berthelot's S_2O_7. SO_4, however, in spite of its ready decomposition into oxygen and sulphuric anhydride, is but a weak oxidising agent. But under certain circumstances it acts as a powerful reducing agent. For instance, if an emulsion of peroxide of lead in 40 per cent. sulphuric acid is brought in contact with a quantity of similar acid which has been been subjected to electrolysis so as to charge it with SO_4, a rapid evolution of oxygen gas occurs, and the peroxide of lead is converted into ordinary sulphate of lead. Prof. Traube regards sulphur peroxide as built up on the type $SO_2(O_2)$, resembling hydrogen peroxide, H_2O_2. He considers that Bertholet's oxide S_2O_7 is a molecular compound of SO_3 and SO_4, for it does not dissolve in water without decomposition, breaking up into sulphuric anhydride and oxygen, which is evolved. On the other hand, it appears, like SO_4, to be perfectly stable in a moderately concentrated solution of sulphuric acid.

THE HISTORICAL DEVELOPMENT OF THE INDUCTION COIL AND TRANSFORMER.

BY DR. J. A. FLEMING, M.A.

(Continued from Vol. XXVI., page 417.)

§ 7. **Callan's Further Researches.**—In the *Philosophical Magazine* for December, 1836, Prof. N. J. Callan made further mention of his auto-induction coils, giving also a description of an improved form of galvanic battery. He wound, on an iron bar about two feet long and an inch thick, two coils of insulated wire, each about 200ft. long. These insulated wires were joined together in series, and the extremities of one wire were put in connection with a battery of 14 cells; on taking hold of the ends of the whole length of 400ft. of wire and breaking the battery circuit, a very sharp shock was felt. He concluded that if about 2,000ft. of wire were so coiled on a bar, and the first 200ft. of this wire connected to a battery, a still greater shock would be received if the ends of the whole 2,000ft. were touched, and the battery contact broken. Twenty-one years afterwards he returned again to the subject of induction apparatus, and in a long Paper, communicated to the British Association at its Dublin meeting in 1857, and reprinted in the *Philosophical Magazine* for November, 1857, Callan described many experiments he had made in his efforts to improve the induction coil and exalt its power. Referring first to the induction coil made at Maynooth College in 1836, and to one like it sent to Mr. Sturgeon in the summer of 1837, he establishes his claims to priority in the matter of the invention of an induction coil, having two *separate* wires, one thick and the other thin, by means of which a *quantity* current could be made to produce an *intensity* current. This 1857 Paper is occupied chiefly in advocating the use of an induction coil, with a secondary circuit made of insulated iron wire, and such a coil he showed to the British Association, in which the secondary circuit consisted of 21,000ft. of iron wire, about ·01in. diameter. His arrangement apparently consisted in using a secondary circuit of insulated iron wire rolled up tightly into a cylindrical form, and which formed not only the secondary circuit, but also the iron core of the primary. The primary circuit, consisting of insulated copper wire, was wound over and outside of the iron wire secondary, and the secondary circuit thus fulfilled at once the functions of core and secondary circuit. In one form of coil described the circuits were alternately overlaid. First an iron wire secondary circuit, then a copper wire primary; then over this another iron wire secondary, and a further copper wire primary. The primary circuits were to be joined in series, and the iron wire secondaries in parallel, with the object of obtaining "considerable quantity" in the secondary currents. It is suggested that in this way it would be possible to procure current enough to operate an arc light between carbon poles. One form of induction coil suggested consisted of an iron wire secondary coil wound up tightly into a helix; and on this, considered as an iron core, the copper wire primary was wound; over this copper circuit another iron wire circuit was coiled, and the two iron wire circuits were joined up in series, so that the copper wire primary acted inductively on both, and generated induced currents in each in the same direction. Reasons are given in this Paper which led the writer to consider that this insulated iron wire secondary circuit had advantages over a secondary circuit of copper wire, and an independent longitudinally divided iron core, as introduced by Backhoffner. Callan explained with great clearness that the principle of joining together the secondary circuits of a number of coils in parallel is the right method to adopt to obtain a secondary current of sufficient strength and electromotive force to produce an arc light, and he may, therefore, be credited with the knowledge at that date of the mode of adding up either the electromotive forces or the currents in the secondary circuits of a number of distinct induction coils. It is not quite equally clear whether he ever arranged his coils with primary circuits in parallel also. The same Paper also contains suggestions as to mode of manufacture of condensers for induction coils, and certain advantages are claimed for condensers made of iron plates rather than of tinfoil sheets. Callan's mode of insulating the wires of his coils was ingenious. He dragged the bare iron or copper wire through a hot bath of melted resin and beeswax, and this, when set, formed a highly insulating and sufficiently flexible varnish on the wire, which appears to have rendered silk or cotton covering unnecessary. The secondary circuits were wound on the plan, previously suggested by Poggendorff, of building up the secondary circuit of flat or vertical coils, so connected that no contiguous parts of the wire were at great differences of potential when the coil was in action.

Prof. Francis Lennon has given* the following details of the remains of Prof. Callan's apparatus, which are still preserved at Maynooth College as valuable relics. The large electromagnet constructed by Callan in 1836, consisting of a horse-shoe of iron, about 13ft. in length, and weighing 210lb., is still in existence (*see* Fig. 12), but it has been deprived in course of time of one of its circuits, so that it now remains as a simple and not a compound electromagnet. A somewhat smaller horse-shoe magnet, constructed by him on the same principle, with two wire coils, one thick and one thin, was the one presented

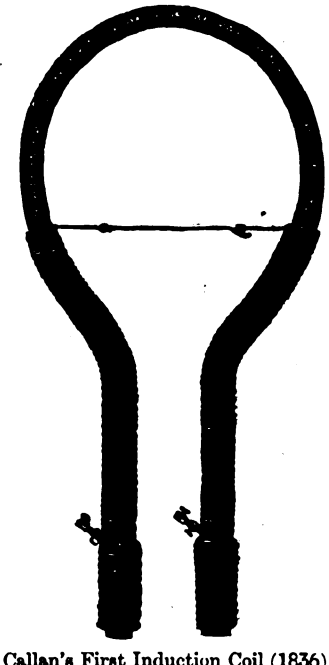

FIG. 12.—Dr. Callan's First Induction Coil (1836), with thick and thin wire Circuits.
Still preserved at Maynooth College.

to Mr. Sturgeon. In the Physical Laboratory at Maynooth also exists one of Callan's Electromagnetic "Repeaters," which was one of the first rapid contact breakers ever made.

§ 8. **Callan's Great Induction Coil.**—The most valuable relic is, however, the large induction coil, which may be regarded as the completion of Dr. Callan's labours. Although constructed 30 years ago, it is still one of the largest coils in existence. The representation of it in Fig. 13 is from a photograph recently made. The core is a cylindrical bundle of annealed iron wires 42in. in length, and 3·5in. in diameter. The thickness of each wire is $\frac{3}{16}$in. The primary coil is a copper wire, ·25in. in diameter, covered with cotton thread, and wound in three layers. For insulation the primary coil is covered with several layers of thin sheet gutta-percha, cemented by a paste, formed by dissolving gutta-percha, resin, and wax in boiling oil. The secondary coil is of *iron* wire ·01in. diameter, and consists of three separate coils or rings. The inner diameter of each coil or ring is 5·75in., and the outer diameter is 21in. Two of the rings are 3in. in thickness, and one is 4in. The rings are so arranged on the primary coil as to divide its entire length into four equal parts, the planes of the rings being perpendicular to the axis of the coil. In each ring both ends of the wire are

* See *Electrician*, March 6, 1891, Vol. XXVI., p. 554.

Digitized by Google

left projecting, so that the separate coils can be joined in series or in parallel. The contact breaker is an automatic mercury break, worked from one extremity of the core. Two condensers, so arranged that they can be used together or separately, serve to reduce the spark at the break. With six cells of the Maynooth or cast iron battery, sparks 15in. long in air can be still obtained, the rings or secondary coils being joined in series. Prof. Gerald Molloy states* that the construction of this coil was commenced by Dr. Callan some years before his death, which occurred in January, 1864, and that it was then left in an unfinished condition. It was probably his intention to add more secondary coils to it. It remained one of the most powerful coils down to the time of the construction of Mr. Apps' large coils for the Polytechnic and for Mr. Spottiswoode. A long Paper by Dr. Callan on the induction apparatus, describing his latest researches, is printed in the *Philosophical Magazine* for 1857, Vol. XIV., 4th series, p. 323. This Paper is full of valuable suggestions and facts.

A description of the large induction coil, and experiments with it, will be found in the *Philosophical Magazine* for June, 1863 (Vol. XXV., Series 5, p. 413). Dr. Callan says that about three years and a-half before the date of writing he made an induction coil of considerable power. The secondary coil was of iron wire, No. 34 gauge, and consisted of three parts, two of which were each about two and a-half inches, and the third three inches long. The entire length of the secondary coil was about eight inches, and it contained 150,000ft. of secondary wire. He used thin sheet gutta-percha in insulating

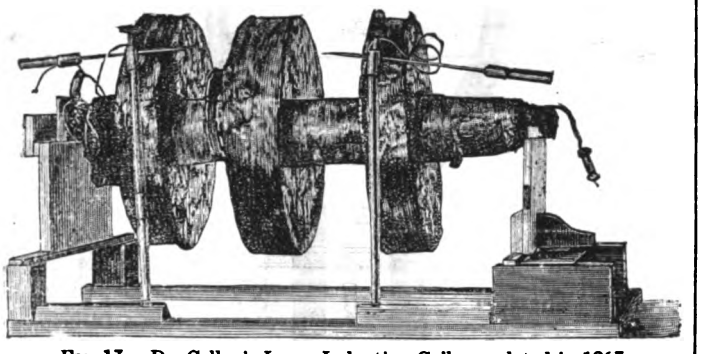

FIG. 13.—Dr. Callan's Large Induction Coil completed in 1863. Still preserved at Maynooth College.

the layers of wire. The primary coil was nearly three feet long, and the soft iron wire core three feet six inches long. This long primary coil was probably intended to be overlaid with more secondary wire, and as left at Dr. Callan's death the coil was incomplete. With three cells of the Maynooth battery this coil would give sparks 15in. in length.

Dr. Callan discovered that an increase in length in the spark is produced by connecting a large plate of any metal to the negative terminal of the coil, and that, in order to get the longest spark, the outer end of the secondary coil should be positive, and the inner end the negative. He states (see *Philosophical Magazine*, June, 1863) that when a pointed wire is connected with the positive end of the secondary a plate connected with the negative end lengthens the spark considerably, but when the point is connected to the negative end and the plate to the positive one the sparks are much shorter. Sparks 15in. long, when the first arrangement is made, are reduced to 11in. with the second. Sparks did not pass at all between positive plate and negative point until the plate was brought within eight and a-half inches from the point.

A ball, three inches in diameter, connected to the positive terminal shortens the spark as much as a 12-in. plate. He noted also that sparks from a positive point to a negative plate never went to the circumference of the plate, and scarcely ever struck the plate at a greater distance from the centre than three inches. But sparks between a negative point and positive plate always went to the circumference until the plate was brought to within two and a-half or three inches of the point; even when a rectangular plate 20in. by 28in. was used as the positive terminal the sparks flew to the edge of the plate.

§ 9. **C. G. Page's Researches in Electro-Magnetism.**—Very nearly at the same time that Prof. Callan, of Maynooth, was assiduously engaged in England in experimental inquiries on the induction coil, Dr. C. G. Page, at Salem and at Washington, in the United States, prosecuted with the greatest zeal and ingenuity similar researches on the other side of the Atlantic. Reference has already been made to his experiments with the ribbon coils of Henry, and which are described in *Silliman's American Journal of Science*, Vol. XXXI., for 1837, in a Paper dated Salem, May 11th, 1836, and entitled "Method of Increasing Shocks, and Experiments with Prof. Henry's Apparatus for obtaining Sparks and Shocks from the Calorimeter." In a second Paper, dated April 24, 1837, Page describes the construction of a large auto-induction ribbon coil, such as has already been described in § 2, which he now calls a "Dynamic Multiplier." This last coil consisted of a single ribbon of copper, 320ft. in length and one inch in width, wound into a flat spiral, the successive turns being insulated with strips of varnished cotton cloth. It had ten mercury cups soldered to the strip at various distances. With this apparatus he repeated all his former experiments on a larger scale. At this stage Page made an important contribution to the subject by inventing various forms of self-acting contact breakers to interrupt the primary current. One of the first of these (made in 1837) was a copper spur, or star wheel, the points of which just dipped into mercury contained in a little gutter or excavation in the base board which supported the wheel. He made this self-acting by placing a horse-shoe magnet so that its poles lay on opposite sides of the wheel, as in the experiment known as Barlow's revolving spur wheel. The electro-magnetic action of

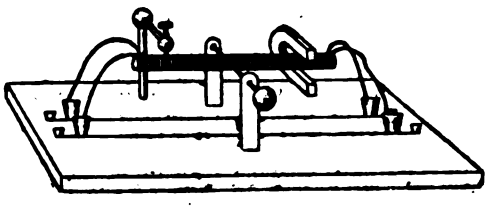

FIG. 14.—Page's Automatic Contact Breaker.

the radial current in the wheel on the fixed magnetic field caused rapid rotation of the copper spur wheel, and, hence, interruption of the current, as the tips of the stellate projections of the wheel passed into and out of the mercury. He found this arrangement to answer well for interrupting a current when powerful currents were used. Such an arrangement, however, failed with feebler currents, and he accordingly devised a rocking magnet interrupter, which he describes in this same Paper, published in 1837, and which was afterwards reproduced almost identically by Golding Bird as his own invention in 1838 (*see* Golding Bird, *Phil. Mag.*, Vol. XII., 1838). Page's contact breaker and Bird's reproduction of it consisted of a small electro-magnet (*see* Fig. 14) made of a piece of soft iron wire, one-eighth of an inch in diameter and three inches long, wound over in opposite ways with two separate insulated wires, the ends of one coil projecting at one end, and the ends of the second coil at the other. This small electro-magnet was balanced beam fashion on pivots, and so arranged that the projecting ends of the wires wound on it could dip in pairs of mercury cups at the two ends of the supporting board, according as the beam was tilted one way or the other. A permanent horse-shoe magnet was fixed so that one end of the beam electro-magnet could play between the poles. The mercury cups on the board were connected together, as shown in the figure. If a battery and coil were connected in series with one pair of mercury cups at one end of the board, it is obvious that matters could be so arranged that the reversals of polarity of the beam magnet as it was caused to tip its connections backwards and forwards into one or other set of cups, could not only maintain the rocking motion, but also interrupt the circuit of the coil. In the following year, 1838, Page had

* See *Electrician*, February 13, 1891, Vol. XXVI., p. 465.

Digitized by Google

completed new and more perfect induction coils, consisting of two separate circuits, a thick wire primary, and a thin wire secondary, and he describes these coils in a very able Paper, published in June, 1838, in *Silliman's American Journal of Science*, Vol. XXXIV., July, 1838, p. 364.

He calls iron cores wound over with two separate circuits "compound electro-magnets," in the use of which phrase he followed Prof. Joseph Henry. These compound electro-magnets, or induction coils, were made with cores, consisting of bundles of fine soft iron wire, or strips of soft hoop iron. The cores were either straight or U-shaped. Dr. Page evidently arrived by independent investigations at a knowledge of the advantage obtained by using such divided iron cores, but whether before or after Backhoffner it is impossible to say. Page himself states that he used them before February, 1838, when Backhoffner first used them in England. These compound magnets were, however, induction coils of the form employed by Callan, and by their use Page obtained visible sparks from the secondary circuits, as well as very severe shocks, and produced secondary sparks by the help even of a primary current derived merely from one or two thermo-electric couples. In this same Paper, Page describes a remarkably interesting and ingenious induction coil which he called a "magneto-electric multiplier." He arrived by experiment at the conclusion that when an armature of soft iron was applied to one of his U-shaped compound magnets, the induction, as we now call it, through the secondary circuit for a given current strength in the primary, was much greater than when the armature was not present. Also

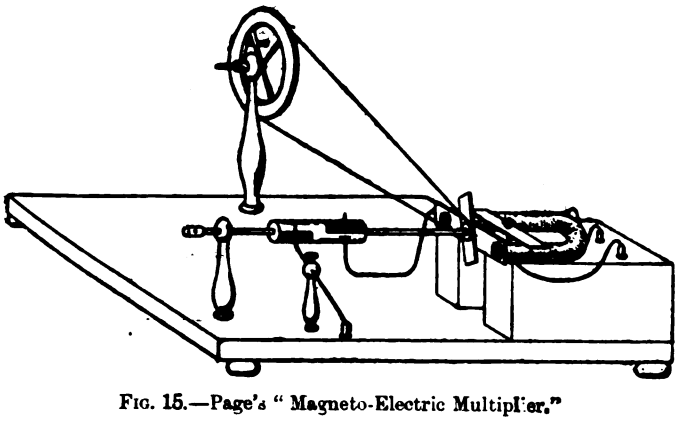

FIG. 15.—Page's "Magneto-Electric Multiplier."

that the depolarising power of the magnet was much greater when the armature was removed, so as to break the magnetic circuit. Hence it occurred to him that if he could first of all make his iron core a closed magnetic circuit *before* starting the primary current, and then break the primary circuit and open the magnetic circuit by detaching the armature directly afterwards, the combination of these two actions would put in and take out of the secondary circuit many more lines of force in the same time, and hence produce a greater electromotive force in the secondary circuit than if the primary circuit of a straight coil were simply opened and closed. This reasoning shows that at this date Page had acquired a great grasp of the true principles of electro-magnetism. The apparatus with which he put his ideas to the test is shown in Fig. 15. It consisted of a horse-shoe shaped induction coil, or a U-shaped compound magnet, the core being made of 500 soft iron wires, 12 inches long, and bent into the shape of a U. The primary coil consisted of five layers of No. 16 copper wire, and the secondary of seven layers of No. 26 copper wire, both being well insulated. This horse-shoe magnet was fixed on a wood block, so that its poles projected horizontally, and a soft iron armature fixed to a spindle, so adjusted that it could revolve in front of the poles. This spindle also carried a cylindrical wooden piece, having brass strips on parts of its circumference, and which had contacts made against it by a couple of brass springs. This was the primary current contact-breaker. By shifting the angular position of this cylinder relatively to the armature, it was possible to break the primary circuit at an instant corresponding to any defined position of the soft iron armature. It was normally set so as to break the circuit of the primary current when the soft iron armature was just leaving the position in which it magnetically completed the iron circuit of the magnet. Hence the primary electric circuit and the magnetic circuit were opened, one immediately after the other. The result was a very considerably greater production of electromotive force in the secondary circuit. Page got brilliant sparks from the ends of the secondary circuit of this coil, and unbearably severe shocks. He was also able to get a small arc when carbon points were used as terminals for the secondary, and he found the tension at the ends of the secondary was great enough to enable him to charge a Leyden jar. The same Paper which contains the description of this "electro-magnetic multiplier" also contains some very clear remarks on the use of divided iron cores, and on the magnetism of soft iron. Page employed sometimes cores made of very soft hoop iron, wrapped together, in making his compound magnets or induction coils. He knew very well that soft iron is capable of retaining a considerable amount of magnetism, provided it is not shaken or twisted. He illustrates this by an experiment in which a very soft iron wire was magnetised by being drawn once across the poles of a permanent magnet. It contains a considerable amount of magnetism if handled gently, and will lift up another piece of soft iron wire equal to itself in weight. If, however, it is given a flip with the finger and thumb, it immediately loses nearly all its magnetism. Page also was aware of the depolarising effect which a number of magnetic filaments, such as magnetised soft

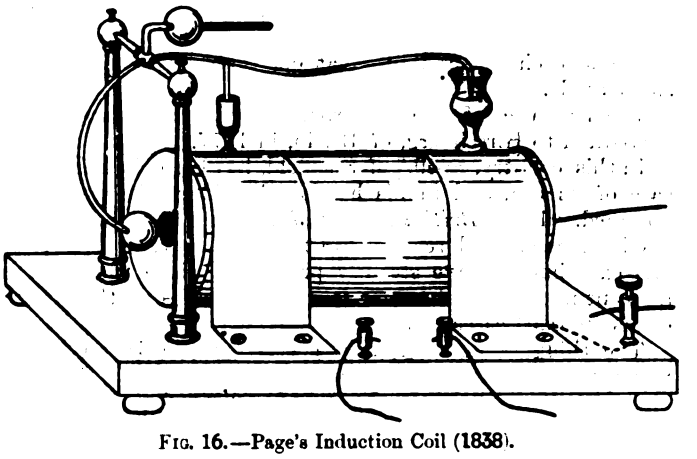

FIG. 16.—Page's Induction Coil (1838).

iron wires, exert on one another when bound into a bundle with similar poles adjacent. On this account, he says, a bundle of fine steel wires will act almost as well as a bundle of fine soft iron wires when used as a core for an induction coil. Page proceeded still more to improve the coil, and in *Silliman's American Journal of Science*, Vol. XXXV., 1839, he communicates another Paper, dated from Washington, Nov. 13, 1838, in which he describes a large induction coil closely resembling modern models. This last coil had a straight core consisting of a bundle of soft iron wires, and the coil wires were wound on a bobbin, having wooden cheeks. The primary wire was a thick copper wire, and the secondary a very fine copper wire. This coil was provided with an automatic hammer break which broke and made a mercury contact (*see* Fig. 16). The hammer head was a ball of soft iron, which was operated by the magnetism of the core. The hammer head was prevented from sticking to the end of the core when attached by the interposition of a small piece of brass. The vibrations of the hammer worked a mercury cup break placed on the coil and which interrupted the primary currents. Page noted the fact that the deflagration of the mercury at the point of break had the effect of prolonging the contact because the primary current continued to flow in the mercurial vapour. Hence, it occurred to him to prevent this by putting oil or alcohol on the top of the mercury to quench the spark and increase the suddenness of the break. This device was revived many years after by other inventors, particularly by Foucault, but it seems first to have been used by Page, in 1838.

THE ELECTRO-MAGNET IN EYE-SURGERY.

BY SILVANUS P. THOMPSON, D.SC., F.R.S.; AND J. TATHAM THOMPSON, M.B., C.M.

For many years past, ophthalmic surgeons have used both steel magnets and electro-magnets. Indeed, the use of the loadstone has been known for two centuries,* for the purpose of extracting from the eyeball chips of iron which have by accident lodged therein, as frequently happens in engineering workshops to fitters and metal turners. Later, in 1745, Dr. Milnes, in his "Observations of Medicine and Surgery," describes how he applied a loadstone to remove a piece of iron from the iris. Probably this was not strictly the case, as he says "immediately it jumped out." It is more likely that he meant that the fragment of iron was embedded in the cornea in front of the iris. According to Hirschberg,† Dr. Meyer, of Minden, was, in 1842, the first to use a magnet in extracting fragments of metal from the actual interior of the eyeball.

In the middle of this century cases of successful removal were recorded by Critchett,‡ Dixon, White, Cooper, and others. There seems to have been little advance until 1874, when Dr. McKeown, of Belfast, recorded in the *British Medical Journal* several successful cases treated by means of a permanent steel magnet tapered at each end to facilitate its introduction.

In 1880, Gruening, of New York, employed a permanent steel magnet composed of a number of "cylinders" (*sic*), united at each end and fitted at one extremity with a needle-shaped pole.

The first use of the electro-magnet in this connection is accredited to Hirschberg, of Berlin, in 1877.

In this country, Snell,‖ of Sheffield, has been the chief advocate of its use, and in his hands splendid results have been obtained. In the *British Medical Journal* for 1881 he describes his instrument and records the results of several operations. His experiments have steadily progressed since then, and in a recent number of the same journal he brings up the number of his recorded cases to 77.

The thing needed for this special service is an electro-magnet which can be fitted with polar appliances of various elongated forms which can be introduced into the wound in the eyeball to a sufficient distance to enable the particle of iron to be attracted and withdrawn. It is necessary at the same time that the electro-magnet should not be too heavy to be conveniently held in the hand of the operating surgeon, and that it should be capable of being excited with current from a battery of moderate size, such as an oculist might be expected to be able to manage and maintain without having to call in a skilled electrician at every occasion of its use. It is obvious that, other things being equal, a magnet of considerable projective power is desirable; hence one with a long core, or with an iron expansion at the posterior end of its core, is preferable to a short one. Possibly in some cases the placing of a mass of iron behind the patient's head during the operation might aid the electro-magnet to project its magnetic field to the desired depth. Various forms of magnets have been devised by various experimenters.

Snell's instrument, which may be quoted as the typical form commonly used by ophthalmic surgeons in this country, consists of a soft iron core surrounded by a coil of insulated copper wire enclosed in an ebonite case. At the one extremity are the terminals for the battery connections, and at the other the soft iron core is tapped to receive the variously shaped and sized needle poles. He recommends the use of a single quart bichromate cell to generate the current.

Hirschberg's instrument consists of a hollow cylindrical core with two curved pointed poles of different thickness for external and internal use.

Bradford, of Boston, devised an instrument almost identical with Snell's, and simultaneously with the latter. It is, however, a much heavier and more powerful agent.

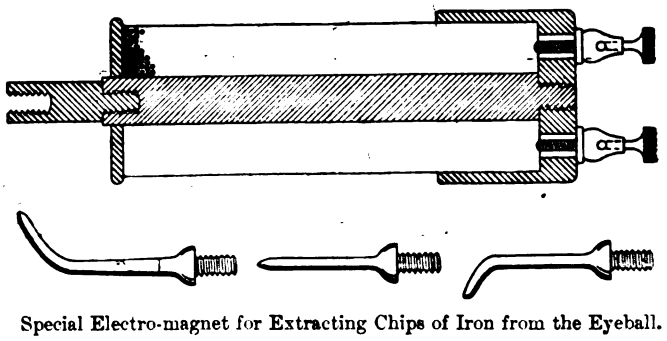
McHardy, of King's College Hospital, used a very similar instrument, but of much reduced size and weight.

The latest form (see Figure below) is that brought out by Tatham Thompson, of Cardiff, and is a further modification of Snell's instrument, but for the same weight and bulk, additional power is claimed, as the magnetic circuit is perfected by means of a collar of iron continuous with the core projecting forwards over the insulated coil towards the manipulative pole piece.

The core is tapped at its extremity to receive the differently shaped poles or an intermediate polar extension where deeper probing is required. The battery used with this consists of one or more quart bichromate "dip" cells. This instrument is shown in the illustration in its actual size, and its weight is only about five ounces.

The most frequent use of the instrument is in removing fragments of steel or iron from the surface or embedded in the coats of the eye, and by its use much disturbance and laceration of the delicate structures is avoided, which the older methods of cutting out or withdrawing by means of forceps, spuds, or curettes, too often involved. Its most valued properties are, however, best demonstrated where it is used for the removal of foreign bodies which have penetrated the walls of the eye. It is not too much to say that in many cases it has been the only possible means of preserving sight.*

In the first place, it is of diagnostic value, for where a fragment, for instance, has perforated the cornea or anterior transparent part of the eye, it can often be proved whether it is steel or iron by observing whether it is acted on by the close approach of the instrument. If no movement is observed, and no peculiar sensation of dragging pain felt by the patient



Special Electro-magnet for Extracting Chips of Iron from the Eyeball.

on the approach of the magnet, it may be due either to its not being a magnetisable metal or to its being gripped by the tissues, or encysted with inflammatory material thrown out by its irritating presence. If in this case a very lightly suspended needle be magnetised and held close to the eye, it may sometimes be found to dip towards the foreign body. If it should chance to be a steel fragment, this effect is greatly increased by holding the electro-magnet close to the eye for a time, so as to magnetise the offending particle.

Further still, the instrument is at times of immense use in moving the fragment from one part of the eye where it is inaccessible, and dropping it in a more favourable position for subsequent removal. For instance, suppose the fragment of steel or iron has penetrated the cornea and lodged in the crystalline lens, it has happened in several cases that by applying the electro-magnet to the cornea the metal has been attracted forward through the lens substance, across the aqueous humour contained in the outer chamber of the eye, and then dropped by opening the circuit on to the floor of the outer chamber; then a small opening being made at the most dependent part, the pole of the instrument introduced there, and the fragment readily removed.

In at least one recorded case a sharp-pointed fragment, which had penetrated deep into the lens, has been seen to force its way

forward through the lens substance and lens capsule, through the iris, and actually be drawn through the cornea, and so removed completely without involving any cutting operation whatever.

It is, however, in those cases where the foreign body has penetrated the posterior or vitreous chamber of the eye that the wonderful results obtained by the electro-magnet are best seen. Where only the outer chamber or the lens is the seat of the mischief, other means may possibly succeed; but when a fragment has penetrated the vitreous chamber, we require an instrument not to go blindly searching round, disturbing the delicate structures and risking the escape of the semifluid contents, but one which will attract to itself the offending particle, and this is where the instrument which we are considering reaches its highest achievements.

Many successful cases have been recorded by Snell, Hirschberg, Lloyd Owen, McHardy, and others, of fragments of steel thus removed from eyes which otherwise must have inevitably been lost.

The most serious and desperate cases of all are where the metal has actually traversed the inner chamber of the eye and become embedded in the delicate retina and choroid lining the posterior wall. So far as can be ascertained, only three successful cases of removal from this position have been recorded. The first by Galezowski in 1882, where a fragment of iron had passed through cornea, iris, and lens, and was lodged in the retina. Its position was noted by means of the ophthalmoscope, an instrument employed by ophthalmologists for examining the interior of the eye. An incision was made in the sclerotic or white coat of the eye over the situation, and the fragment removed by means of the electro-magnet. The second, recorded by Hirschberg in 1888. The third by Tatham Thompson, of Cardiff, in 1890. Some detailed account of this will illustrate the method of the procedure.

The patient was a blacksmith employed at one of the South Wales collieries, and on December 8th, whilst "stamping" a new "pick," was struck on the left eye by a fragment of the new tool. The fragment struck him on the "sclerotic" or white of the eye," about a quarter of an inch from the margin of the cornea. He felt little pain at the time, but two days later dull pain supervened, and considerable irritation and dimness of vision, not only in the injured but in the sound eye.

He was sent to the Cardiff Infirmary on December 10th. When examined there, a small wound was found at the point where the fragment had entered on the inner side, and on ophthalmoscopic examination, the piece of steel could be seen embedded in the retina at the upper and outer part. The track which it had made in traversing the vitreous chamber could also be distinguished by slight opacities in the humour. The uninjured eye showed distinct signs of sympathetic irritation. The next day the patient was put under the influence of ether, the wound of entrance slightly enlarged to allow the introduction of the pole of the electromagnet. This was passed across the vitreous chamber in as nearly as could be calculated the direction originally taken by the fragment. On withdrawing the first time nothing resulted, but at the second attempt the piece of steel came readily through the wound "in tow" of the pole. Only a very small bead of vitreous humour escaped, and the eye was dressed antiseptically and bandaged. At the end of 24 hours he could count fingers at 4ft. distance, was quite free from pain and dread of light, and the dimness of the other eye had largely disappeared. The wound healed in three days, and the sight steadily improved, till on December 30th he could read moderately sized print. Examined by means of the ophthalmoscope, the scar formed in the retina at the point where the fragment had lodged could be distinctly made out, as well as some patches of hæmorrhage caused either by injury from impact of the fragment or by injury of retinal vessels at the time of its removal.

On January 13, 1891, he could read small print; his central vision, in fact, was as good as ever, but his "field of vision" was limited slightly below—the limitation corresponding to the portion of retina injured by the foreign body.

The electro-magnet has been used also to some extent in general surgery for the removal of needles from the soft tissues of the body or limbs.

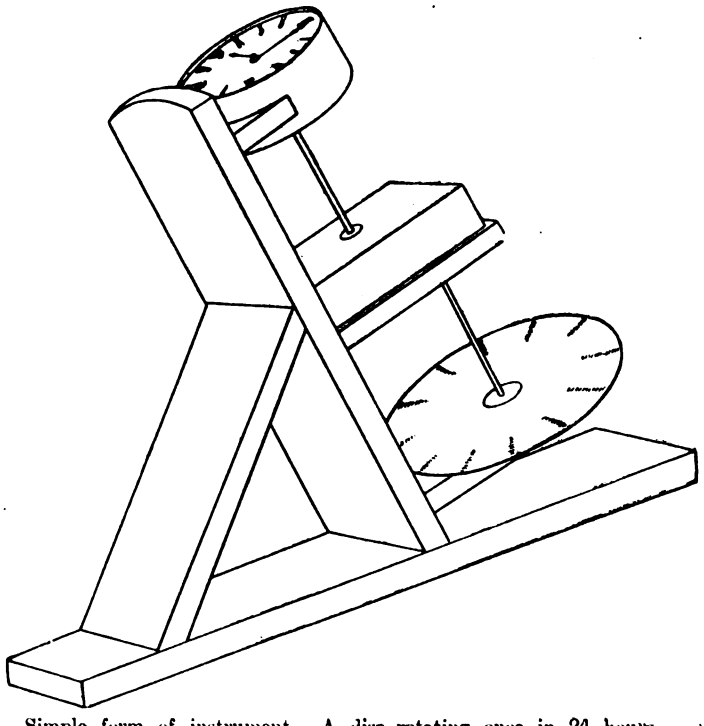
PHYSICAL SOCIETY.

At the meeting of this Society on June 12th, Prof. O. Lodge, F.R.S., exhibited and described

'A Clock for Pointing out the Direction of the Earth's Orbital Motion in the Ether."

After observing that his attention was directed to this matter by some problems relating to aberration, he said that a point on the earth's surface was always moving to the west, in virtue of the diurnal rotation of the earth, at a speed of 700 miles an hour. At the same time it was being carried in the plane of the ecliptic in a direction at right angles to the sun at a speed of 19 miles a second, while the whole solar system is supposed to be moving towards a point in the constellation of Hercules at a speed of about five miles a second. This combination of motions was not easy to conceive.

An apparatus for pointing out this direction was, therefore, convenient when dealing with problems requiring a knowledge of the motion of a point through the ether. A simple and early form is shown in the figure, and in the more elaborate form one spindle, representing the earth's polar axis, and another the axis of the ecliptic, were inclined at an angle of 23½deg., and coupled by a Hooke's joint. The latter axis was capable of rotating round the former. At its upper end the ecliptic axis carried a tube and a



Simple form of instrument. A disc rotating once in 24 hours graduated to show the dates throughout the year. On any given date the radius corresponding to that date points in the required direction.

pointer, both being perpendicular to the axis and to each other. The clock keeping solar time rotated both axes, and when properly set the tube pointed in the direction of the sun, and the pointer, therefore, indicated the direction of the earth's orbital motion.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

FRIDAY, June 26th.

PHYSICAL SOCIETY OF LONDON.

5 p.m. Ordinary Meeting. Papers to be read: (1) "The Construction of Non-Inductive Resistances." By Prof. W. E. Ayrton and T. Mather. (2) "The Influence o Surface-Loading on the Flexure of Beams." By C. A Carus-Wilson. (3) "On Pocket Electrometers." By C. V. Boys. (4) "On Electrification due to the Contact of Gases with Liquids." By J. Enright.

ROYAL INSTITUTION.

9 p.m. Faraday Commemoration Lecture. By Prof. Dewar, F.R.S

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements should be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday.*

SMALL PREPAID ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1891 Edition, published on the 23rd February, 1891, consists of 900 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with well-written Biographical Notices of leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1891 should be ordered at once. Price 5s., post free 5s. 9d. Abroad postage extra. Prospectuses free.

ELECTRICAL BOOKS AND PUBLICATIONS

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

"THE ELECTRICIAN" *Series at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING. Vol. I. Price 7s. 6d., post free.

THE EDISON LAMP PATENTS.

Once more, and probably for the last time, the EDISON lamp patent has appeared in the law courts; not here, fortunately, but in the United States. The case is of a protean nature, depending as it does on the country in which it is tried, the patent laws of that country, and the parties to the action. On no two occasions, during the many independent trials which have been held, have the same points been urged, or the same standpoint adopted. The WOODHOUSE and RAWSON case of 1886, which might have settled the question, as far as the English interests are concerned, was bungled in a most unsatisfactory manner; unsatisfactory to the plaintiffs since they had to fight again in 1888, and unsatisfactory to the defendants who lost their case and their lamp-making business. EDISON *v.* WOODHOUSE and RAWSON degenerated into an uninteresting dispute about the definition of a filament, a definition which was dismissed as being quite unimportant in EDISON *v.* HOLLAND, but which was reinstated in the appeal and reversed the judgment of Mr. Justice KAY. In EDISON *v.* HOLLAND, the EDISON and SWAN interests were united, and arguments were based upon such details of the work of those two inventors as were calculated to support the monopoly.

While united against a common opponent in this country, a law-suit was being carried on in Germany at the same time, between the EDISON and the SWAN Companies, and the evidence on some points could hardly be recognised as being based upon the same facts as those which were brought forward in the English law courts. The result denied to EDISON the rights of exclusive manufacture of glow lamps, and confined those rights to lamps of the kind which he described. The present trial in the Southern District

Digitized by Google

Circuit Court of New York seems to follow the lines of EDISON *v.* HOLLAND, rather than the SAWYER-MANN and other American suits. No originality is to be looked for in the judgment, for almost every possible decision has been given already by some judge or other, and it is difficult to feel much interest in the outcome of the controversy.

The present case has opened with a very elaborate speech, which attempts to impart to the judge a schoolboy's knowledge of elementary electricity, and an elaborate *resumé* of the history of the invention of the modern glow lamp. A superficial glance at this speech conveys the idea that this, like the other law-suits, is founded upon an accurate recital of the events which led to the invention. As a matter of fact, a number of interesting, and, for the most part, isolated bits of history are dug up, and after a little trimming and preparation, depending on the purpose for which they are required, they are presented by counsel or witness to the judge and to the public. But when we come to watch more closely, we soon find that neither judge nor counsel want to bother themselves with mere history of scientific work, but are really concerned, as of course it is their business to be, with the chronology of the patents. From their point of view this is natural, since, on the one hand, the patenting of an invention is the only proof of proprietorship that the legal mind is concerned with, and the history of an invention, prior to its patenting, is only to be considered in cases of prior publication. Although the patent is supposed to be granted only to the first and true inventor, the private work in a laboratory and the exhibition of the results to a few visitors is not, legally, of any account. By such work the result, and, indeed, a far more developed and useful result, may be achieved, but the author is not entitled to be called the first and true inventor unless he pays a fee to the State, or else throws open the result of his labour to the public.

As a matter of history it is well known that SWAN hit on the use of carbon, made lamps with carbon filaments, and LANE-FOX recognised the economical importance of high resistance before EDISON did. Had EDISON worked with as little ostentation as SWAN, there would have been a difficulty in arriving at this conclusion, but all the world was ringing with the marvellous platinum lamp which was the immediate cause of the panic among the shareholders of gas companies. LANE-FOX had given platinum a fair trial, and knew its weak points; SWAN had made patient experiments with carbon, and was just arriving at success, being convinced that carbon was the right material to use, while the daily papers were full of EDISON's wonderful "subdivision" of the electric light. EDISON applied for ten patents for electrical inventions in this country during the years 1878 and 1879, six of these relating to electric light. SWAN applied for no electrical patents until 1880, though in 1879 he patented several inventions in connection with the equally important discovery of the gelatine photographic dry plate. We should not be surprised if EDISON wins again, since it is probable that his claims are justified legally, on account of the large number of patents which he has taken out. It would be strange if none of them could be found to cover the more important parts of the lamps with which he was experimenting at that time. But this has little or nothing to do with the credit of priority which is esteemed highly by all inventors, and too highly by some of them. It is an historical fact, which bears slightly, if at all, on the legal question, that EDISON's much be-puffed platinum lamp, which proved to be quite worthless, gave rise to a panic in the shares of gas companies in January, 1879. At this time, SWAN was already on the road to success with horse-shoe filaments of carbon, and in the following month he exhibited them at the Literary and Philosophical Institute, at Newcastle. But SWAN did not venture to patent his imperfect attempts; he was fully alive to their defects, and waited for something better. Had he filed a clever specification for these horse-shoe filaments he would undoubtedly have been master of the situation. In October 8, he received a letter from a friend who, alluding to EDISON's experiments, said "he has trodden so closely on our ground that, if he has patented his process, I am afraid he has anticipated you entirely." And it has been held that EDISON did so anticipate SWAN. But was the anticipation a patent or an invention? It was a mere patent. It described a closely coiled filament of a putty of tar, and no lamp has ever been shown which was made under that patent, except for purposes of litigation; and the amount of combined talent which was expended by some of our best men in striving to make, according to that patent, something which they could swear was a lamp, would, if expended on improving the glow lamp in 1879, have assisted its development to a very marked degree.

The principle laid down by Lord ELDON, that a patent is a bargain between the public (represented by the Crown) and the patentee is generally recognised, and one of the conditions of the bargain is that the patentee should clearly describe the best method known to him of performing the invention. "The best method" premises a good method, but we cannot believe that EDISON, in his most sanguine mood, could ever have thought that the tar-putty filament was a practicable one. It was a step, as was the paper horse-shoe of SWAN, which was a superior affair, and which, with but slight modification, is still to be seen in the MAXIM lamp. We know of no trace of tar-putty filaments to-day, or of anything which can be said to be a development of them. Nor is the bamboo lamp, that remarkable outcome of the patient and untiring experimenting for which EDISON is so justly famed, to be found in ordinary use. Our glow lamp is the direct outcome of SWAN's further work, which, when really promising success, and fit to publish, he lost no time in protecting, as the patent record of 1880 shows.

As for the "bargain between the patentee and the public," and his "clear description," it is mere irony in the case of EDISON's patent. And even to-day the lamp patents disclose as little as possible; the useful and important points which go to make a good lamp are jealously guarded trade secrets, in direct opposition to the principle of patents.

ELECTRIC AND MAGNETIC THEORIES.

BY JOHN T. SPRAGUE.

(Concluded from page 190.)

§ 17. In considering Figs. 12—14, p. 132, we need a starting-point, which Prof. Thompson fails to supply. Do these lines and planes originate at the wire, and spread out into space to unknown distances? That is the common-sense view, and it is that of my theory, for these lines are merely the dotted lines I of static stress, and M of magnetic stress of my Fig. 2, reproduced on p. 161. But, as I understand the new theory, they must be constructed from outer space, and flow in towards the wire. So this brings us back to the old question, what is it in the wire which causes it to draw energy towards it which has started away on a radiant course? I take it we shall all agree that an effect cannot be its own cause. Therefore, radiant energy cannot itself construct these equipotential paths by which it is to be carried back towards the wire. It can construct them, by an action gradually extending from the wire, as a foundation, through layer after layer of the surrounding matter. But even if we admit the transfer from P to Q, Fig. 14, we have not yet got the energy to P, along, say, that 1,000 miles of space from the source. How often does it "swirl" on the road?

Digitized by Google

§ 18. Prof. Thompson, on p. 160, Figs. 15 and 16, lays out some imaginary difficulty in my way, and "puts it forward as a cardinal point in the controversy." I accept it, and claim it as a new proof of my theory. Fig. 16 appears to be a diagram of a common experiment, a great favourite of young gutter philosophers, who put a little stick across the flowing water and produce the small whirlpools shown. Fig. 15 shows an electric current as observed under similar circumstances. I must thank Dr. Lodge for this illustration, and will ask his permission to use it when I want to show how my theory has been proved correct by him, and am obliged to Prof. Thompson for specially directing my notice to it. Why, those observed lines are actually my polar chains of current? and they are very neatly worked out again in Fig. 17. I may as well remark that the term "end thrust" is not my term at all, and that nowhere have I suggested that what we call "electric current" involves a motion of translation; on the contrary, I have always maintained that the motion is one of rotation of molecules within a line, and not one of translation. Therefore it does not involve the production of the "swirling eddies," shown in Fig. 16 and in the gutters; it does involve "stream lines symmetrical in front of and behind the obstacle," as in Figs. 15 and 17. I do not know that we are limited to Dr. Lodge's "three possible alternatives," and I do not see that No. 3 of these, "the propelling force acts at every point of the path," is in any way inconsistent with my theory, that it is by means of the internal forces of all the molecules forming the circuit that electrical phenomena are produced. The considerations in § 20 would have more weight if these "stream lines" were really continuously existent during current; but this they cannot be. They are each set up, on my theory, by energy impressed on them at the source, by chemical actions among infinitesimally small particles of matter, or by each rotation in a field of force; each such impulse is complete in itself, not a continuous pressure. The apparent continuity results from the rapid succession of impulses; therefore, there is no difficulty in conceiving the greater rapidity of motion where there is less matter to spread the action over.

§ 19. Having dealt with Prof. Thompson's own arguments and shown that either they do not apply or fail in essentials to meet the problem, I wish I could leave unnoticed the two last columns in which he deals with my articles. I cannot do so, or I should be told I was silenced. But I will ask any impartial person to say whether my arguments are even touched. Prof. Thompson deals some "swashing blows," but they fall on a thing of shreds and patches, a scarecrow of his own device, in which I can hardly trace even a bad caricature likeness to my production.

My Fig. 2, reproduced to demolish, is a mere outline index to my arguments, in no way offered as itself explanatory; the long current arrow is merely the conventional symbol of electric current; the dotted lines, I, merely indicate static stresses actually existing from all parts to all parts of the circuit; the special forms of the arrows have no occult meaning calling for any "Good gracious, what are we coming to?" I am afraid I might borrow those words as to the criticism on my poor four energy arrows and their offsets, for this at least is certain, they represent the fact that the energy is simultaneously distributed in both directions along the circuit, irrespective of any theory as to the nature of current. If Prof. Thompson cannot understand the voltameter, I am in the same condition as to his criticism. Does he suggest that current does not traverse voltameters just as it does a battery, only expending energy instead of gaining it, which is just what my figure shows?

He retorts my question as to how the energy knows where it is wanted, but his question has no meaning. I have shown the limiting paths for the energy, and the calls upon it (like toll bars) compelling it to pay for its carriage as it goes. He merely says it goes to those places, without giving any reason why it should, or any mode by which it is compelled to. I am not going to be led off into Hertz experiments just now. I hope, when I have time, to write some Papers on "a common-sense study of the Hertz experiments;" just now they would simply introduce confusion.

§ 20. But I am willing to give a problem. The one special difference between Hertz and other experimenters on induction, is the use he has made of "reflection" from surfaces, and the generation by its aid of "nodal" points; this reflection is another form of what has been studied under the name of screens and shielding. Now will Prof. Thompson construct a screen or reflection surrounding the fine wire in his Fig. 9 and secure total reflector of the energy streams (an imaginary one will do, and is more easily made perfect by the formula "let us conceive")? Will he tell us that now energy is shut off from outside, his fine wire will no longer get heated? Will he deny that the current and energy will go on unaffected, save by any change which may be produced in the resistance of the wire as due to heat?

§ 21. I suppose Prof. Thompson would call his comments upon my hydraulic analogy criticism. I do not. Would he write a review of that collection of truths, Æsop's fables, and begin with, "Does this author really expect us to accept all this nonsense as fact?—if so, he should have obtained sworn copies of the shorthand writer's notes, or, better still, a phonogram of the asserted conversations"? Would that be a bit more absurd and unfair than his, "what trifling all this is. Are the copper conductors elastic? Do they swell up or contract in order to produce the effects of surface charge, magnetic stresses, and the like?" The question is whether my analogy, treated with reasonable intelligence, does convey a clear meaning; analogy is not identity; my analogy was meant to show a mechanical process, absorbing and storing energy, and bringing about results, in masses of matter, resembling those produced electrically among the molecules of matter. Had it not been a thoroughly good one, and one which cannot be answered, it would have been answered instead of being ridiculed without reason. As to all the rest, I carefully separated stress and flux, variable periods and steady currents, the conductive and dielectric functions of matter, and directed consideration to each separately. Prof. Thompson pitchforks them all together, and then complains that any particular scrap he picks out does not meet the whole case. Will he or someone now give us an explanation of what the new theory really does mean?

THE FRANKFORT EXHIBITION.

The principal exhibitors have now made considerable progress with their exhibits, and in the Machine Hall, which was, of course, the most backward, all the firms, with the exception of Siemens and Halske, and the Lahmeyer Company of Frankfort, have the greater number of their machines running. Schuckert and Co. are setting up a fourth 100 H.P. steam engine; they have already three in full use, including their largest, which gives about 300 H.P., and runs quietly and smoothly at about 145 revolutions per minute, coupled directly to a large ring machine The firm has also a rotary current dynamo, which is to drive a similar motor, both in the Machine Hall, but these are not at work yet; a rotary current motor is, however, running in the hall for the distribution of electricity. Schuckert and Co. do not recognise the term "rotary current machine," but prefer the name of alternating machine with different phases. A model tramway erected by this firm is now in operation, running between the Electrical Distribution Hall and the Marine Exhibition on the Main, a distance of about 150 yards. The system resembles the Lineff very closely.

A Berlin firm, Naglo Brothers, occupy the space next to the Schuckert Company; they have been in full work for some time, but their exhibits, though very well arranged, are not amongst the most extensive. They have an 80 H.P. steam engine, to which is coupled direct an interior pole machine, and two dynamos are driven by belting by the same engine; the latter are drum armature shunt machines, and are provided with an automatic switch for putting either machine out of circuit in case of inequality of pressure. These dynamos supply current to 500 Swan glow lamps and 24 arc lamps. Adjacent to the last named firm, the Esslingen factory are showing an eight-pole dynamo for the five-wire system (480 volts × 124 amperes) running directly coupled to a 100 H.P. engine. This machine supplies current to a motor in the pumping house on

Digitized by Google

the Main, the motor being of the interior-pole type, and of 50 H.P., as well as to arc and glow lamps on the five-wire mains.

The Thomson-Houston Company have one dynamo now at work in the Machine Hall, driven by a 30 H.P. gas engine, by a Munich company. Their machine seems to attract much attention from Germans, which, perhaps, is not entirely due to the brilliant coruscations at the brushes. Their latest electricity meter is also a centre of attraction. This Company have begun setting up their pumping-house installation, which lies well at the back of the Exhibition. They are just setting up a dynamo-motor, driven by the dynamo in the Machine Hall, actuated by pulsating currents; this will, in its turn, drive a pump, consisting of a piston and cylinder, in which coils are inserted; these, by means of the varying current, attract and repel the iron core of the piston alternately, giving about 300 strokes per minute.

Under a signboard marked "Woodhouse and Rawson," Messrs. Ruston and Proctor, of Lincoln, have a space allotted to them in the Machine Hall, next to the Thomson-Houston Company. A Kingdon alternator, belted to a 60 H.P. horizontal compound engine with automatic expansion and a "Porter" regulator, forms their chief exhibit. Messrs. Lahmeyer, of Frankfort, are busily at work erecting a high-pressure central station, and this bids fair to be one of the most interesting in the Machinery Hall. When this firm's exhibits are all *in situ*, they will include a high-pressure dynamo (660 volts × 110 amperes) driven by a 100 H.P. compound condensing engine, a similar but smaller dynamo driven by a Westinghouse engine, and a low-pressure exciter driven by a triple expansion 30 H.P. engine.

The exhibit of the Helios Company of Cologne is in full working order. Their great 2,000-volt 600 H.P. alternator has proved a great success, and forms the great centre-point of attraction in the hall. This machine lights up the dome of the hall with hundreds of glow lamps, besides supplying current for arc lamps and motors. The Helios Company are particularly well favoured in position; they have the very centre of the hall, and almost divide it into two parts, and their exhibit is visible from three sides.

Siemens and Halske, whose exhibit must have cost a considerable sum, have a good position at the extreme end of the hall. Fresh plant seems to arrive for them every day, and they are rapidly bringing their installation to completion. Their direct-current 330-kilowatt machine is already set up, but not in use. This machine, with the above load, is to run at 100 revolutions per minute, but if necessary the load may be increased to 500 kilowatts. It is the largest direct-current machine yet in Germany; the armature has an outside diameter of 9ft. 9in. It is an interior 10-pole machine. The great alternator of this firm is also ready. The outside diameter of the armature is about 15ft., while that of the ring on which the magnet coils revolve is nearly 12ft.

The importance to which the Schuckert, Helios, and Siemens firms, not to speak of many others, have given to the exhibits in the Machinery Hall, and the extensive way in which nearly all the firms here represented are exhibiting, make this part of the exhibition of the highest interest. It may be worth mentioning that the electrical and other apparatus in the exhibition, not including objects of art, &c., are insured for between two and three hundred thousand pounds, of which sum Siemens and Halske's exhibit represents over £38,000, and Schuckert and Co.'s £30,000.

ELECTRICAL INSTRUMENT MAKING.

II.—PIVOTTED GALVANOMETER.

Where greater delicacy and sensitiveness are required than can be obtained with the instrument described in the preceding article (*The Electrician*, June 5, 1891), and where portability is at the same time a necessity, the instrument now to be considered will be found useful. It belongs to the class in which the needle system turns horizontally on a single pivot.

The outer case, *a a* (Figs. 1 and 2), of the instrument is turned up out of boxwood, and is 4in. in diameter and 2in. deep outside. The inside recess has three different diameter measurements. The lowest part, having a diameter of 3in. and a depth

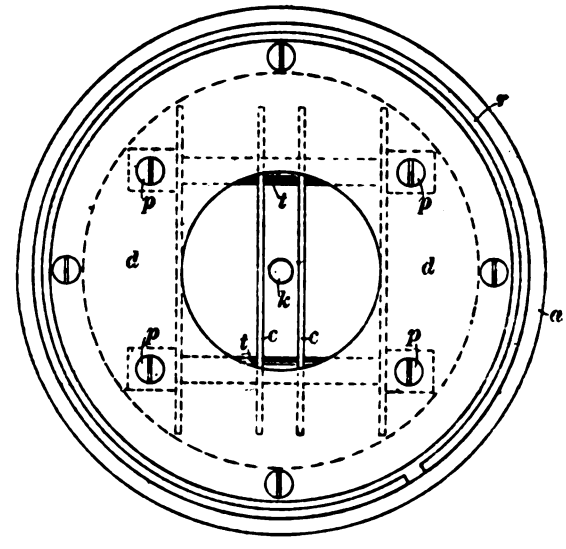

Fig. 1.—Pivotted Galvanometer. Plan.

of 1⅛in., receives the coils. On the bottom of the next section, which is 3½in. in diameter and $\frac{5}{16}$in. deep, the brass dial (*d*) of the instrument is fixed, while the top part of the recess (3¾in. diameter and $\frac{3}{16}$in. deep) contains the glass cover *g* and its fastening ring *r*.

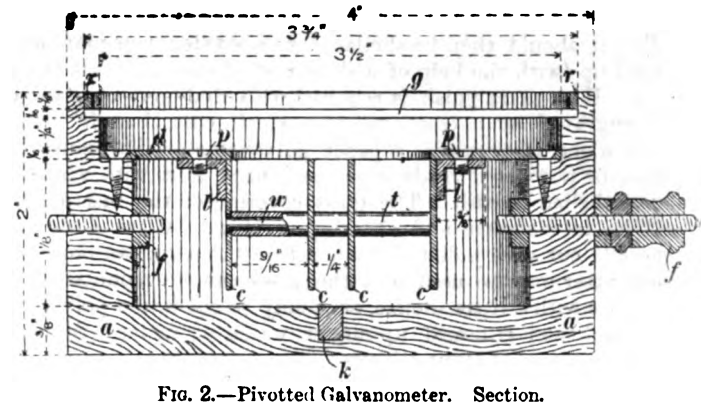

Fig. 2.—Pivotted Galvanometer. Section.

The bobbins upon which the coils are wound are constructed as follows:—*c c* are four brass cheeks, 2½in. × 1in. × $\frac{1}{32}$in., having holes large enough to take a No. 13 wire (about $\frac{1}{10}$in. diameter), drilled ½in. from each end, and equidistant from

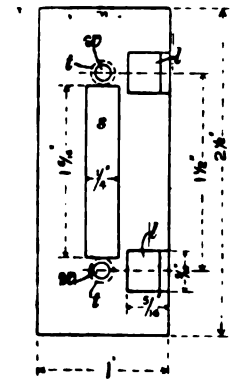

Fig. 3.—Pivotted Galvanometer. Details of Bobbins.

each side; between these holes are slots, *s* (Fig. 3), 1$\frac{5}{16}$in. long by ¼in. wide; *t t* are lengths of brass tube about $\frac{3}{16}$in. external diameter, and of metal sufficiently thin to allow of a straight piece of No. 13 S.W.G. wire being passed through them. The

Digitized by Google

cheeks and the tubes (which serve as separating pieces) are slipped on to pieces of No. 13 brass wire, 1⅝in. long (shown at *w*, Fig. 2). The tubes separating the inner cheeks should be ¼in. long, and those between the inner and outer cheeks $\frac{9}{16}$in. The holes in the outer cheeks should be slightly countersunk on the outside, and the ends of the wires *w*, as soon as the cheeks and tubes are in position, should be riveted over and filed down flush with the surface of the cheeks; *l l* are lugs for fastening the bobbins to the dial *d*, by means of the countersunk screws *r*. The easiest way of making these lugs is to grip a piece of sheet brass in the vice, bend it sharp over, and hammer it about square. Finish it on the angle of the surface-plate, and then file up the back. If the brass is too hard to bend without cracking, make it red hot and drop it into water. The lugs should be soldered to the cheeks in the position shown with soft solder. The surfaces of the lug and cheek should be tinned and held together in position with a small pair of pliers over a Bunsen flame until the solder oozes out from between them. They should then be removed from the flame and cooled. The lugs should, of course, be fixed before the bobbins are put together. In making the cheeks they should be stuck together with shellac, so that they may be all drilled and filed up together. This will ensure of the bobbins being square and true when finished. The best way to make the slots is to drill a row of holes $\frac{3}{16}$in. in diameter, and $\frac{3}{16}$in. from centre to centre, drilling every alternate hole first and then the intermediate ones. The slots may be finished off with a small cold chisel and a file. The brass dial is 3½in. in diameter and $\frac{1}{16}$in. thick ($\frac{3}{32}$in. stuff); it has a circular opening in its centre about 1½in. in diameter. This opening is merely to pass the needle of the instrument through, and is shown circular instead of being simply a slot on account of the greater facility with which it may be thus made.

The dial *d* should be first roughly cut out of a piece of sheet brass and carefully flattened by hammering with a wooden mallet, it should then be shellaced to a wooden face-plate and turned up (with the help of a slide rest, if such a tool is available). If an extra finish is required, this dial may be silvered and engraved at a comparatively small cost, but if plain utility alone is required, a paper galvanometer dial must be drawn, or purchased ready made, and fixed to *d*, with white of egg or shellac varnish. The glass covering of the instrument is 3¾in. in diameter and about $\frac{1}{16}$in. thick. Glass discs are generally cut with a diamond on a turn-table, but an ordinary glass cutter may be used, and the glass can be mounted on a face-plate with a little shellac, or it may be cut into a polygonal form, and then trimmed up under water, or under a running tap, with a pair of stout scissors.

A brass ring, *r*, holds the glass in position. It is made of hard strip brass ⅜in. wide by about $\frac{1}{16}$in. thick; having been cut to the proper length (about 11¾in.) it is bent into a circular form by being coiled round a cylinder about 4in. in diameter, the bending being facilitated especially at the ends of the strip by hammering with a mallet. The ring, when expanded, should be about 4½in. in diameter, and its ends, when compressed to 3¾in., should be about $\frac{1}{8}$in. apart. It is kept in position by its spring. A piece of cork, *k*, Fig. 1., is pushed into a hole made in *a* to receive it; into it the pivot, which consists of No. 6 sewing needle, is pushed, great care being taken to fix it in an absolutely vertical position with regard to the base *a*.

The needle system is shown in Fig. 4; *m* is a piece of glass tube about ⅛in. in diameter and ⅞in. long, with sides as thin as can be obtained; it is drawn to a point at one end—the conical cavity in this end, must not be too sharp, and it must be exactly central or the needle will not swing freely; *n n* are the needles, they each consist of two pieces of watch-spring 1⅜in. long by about $\frac{1}{16}$in. wide. These are magnetised, and each pair is whipped together at each end with sewing silk. Like poles should, of course, be together. These double magnets are then opened out in the middle and slipped over the glass tube. They should be in the same plane and have opposite poles on the same side of the tube, whose centre should, of course, be equidistant from their ends. They should also be in such a position on the tube that when the latter is placed in position on its pivot, the whole system swings freely, and without coming in contact with the bobbins or dial. The upper needle should be about $\frac{1}{16}$in. above the dial. A light pointer of aluminium or very thin sheet brass or copper pointed at each end, and as long as the diameter of the scale, and ⅛in. wide at its centre, is placed over the upper needle and at right angles to it. Both the needles and the pointer should be cemented in position with a thick cement made of sealing-wax dissolved in spirits of wine. As soon as this cement is dry the system should be placed on its pivot (the dial and bobbins having been removed) and carefully balanced by weighting the lower needle and the underside of the pointer as required, with sealing wax, until the tube hangs vertically on the pivot. The ends of the pointer should be slightly bent down towards the dial, as this facilitates accurate reading.

Previously to winding the bobbins the inside of each cheek should be covered with thin notepaper saturated in hot paraffin wax. The separating tubes between the outer and inner cheeks

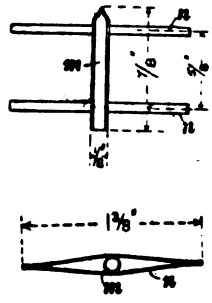

Fig. 4.—Pivotted Galvanometer. Needle system.

should also be covered with paraffined paper until their diameter reaches rather more than ¼in. A core of wood, 2½in. × 1in. × ¼in., well steeped in paraffin wax, should be pushed through the slots and the wire wound on in the usual manner. If fine wire be used, the first layer should not be thinner than No. 22 S.W.G.; over this a layer of notepaper should be placed. As in the last instrument described, each layer of wire should be treated with shellac varnish. The coils should be thoroughly dried before removing the core, and when finished should be covered with green silk ribbon. The ends of the wires should be soldered to the screws of the terminals. Terminals with double nuts, as shown, will be found extremely useful in this instrument.

If great sensitiveness is not required, the needle system need only have one magnetic needle. It will be found useful sometimes to have two needle systems, one astatic and the other single. Most instruments of this type are provided with an arrangement for lifting the needle system off the pivot. The best way to do this in the present case is to turn the instrument upside down when not in use.

The following diagram is Fig. 6 of the first article on "The Linesman's Detector," which appeared in *The Electrician* of

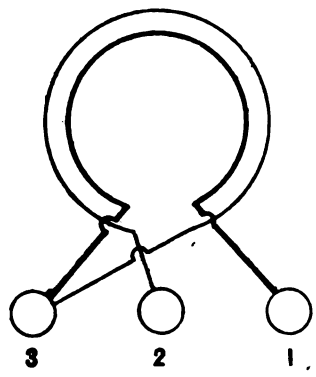

Fig. 6.

June 5th. This figure, which was inadvertently omitted from the article in question, shows the coil connections.

VARIATIONS OF CONDUCTIVITY UNDER ELECTRICAL INFLUENCE.*

BY E. BRANLY.

The object of this article is to describe the first results obtained in an investigation of the variation of resistance of a large number of conductors under various electrical influences. The substances which up to the present have presented the greatest variations in conductivity are the powders or filings of metals. The enormous resistance offered by metal in a state of powder is well known; indeed, if we take a somewhat long column of very fine metallic powder the passage of the current is completely stopped. The increase in the electrical conductivity by pressure of powdered conducting substances is well known, and has had various practical applications. The variations of conductivity, however, which occur on subjecting conducting bodies to various electrical influences have not been previously investigated.

The Effect of Electric Sparks.—Let us take a circuit comprising a single cell, a galvanometer, and some powdered metal enclosed in an ebonite tube of 1 square centimetre cross section and a few centimetres long. Close the extremities of the tube with two cylindrical copper tubes pressing against the powdered metal and connected to the rest of the circuit. If the powder is sufficiently fine, even a very sensitive galvanometer does not show any evidence of a current passing. The resistance is of the order of millions of ohms, although the same metal melted or under pressure would only offer (the dimensions being the same) a resistance equal to a fraction of an ohm. There being, therefore, no current in the circuit, a Leyden jar is discharged at some little distance off, and the abrupt and permanent deflection of the galvanometer needle shows that an immediate and a permanent reduction of the resistance has been caused. The resistance of the metal is no longer to be measured in millions of ohms, but in hundreds. Its conductivity increases with the number and intensity of the sparks.

Some 20 or 30 centimetres from a circuit comprising some metallic filings contained in an ebonite cup, let us place a hollow brass sphere, 15 to 20 centimetres in diameter, insulated by a vertical glass support. The filings offer an enormous resistance and the galvanometer needle remains at zero. But if we bring an electrified stick of resin near the sphere, a little spark will pass between the stick and the sphere, and immediately the needle of the galvanometer is violently jerked and then remains permanently deflected. On some fresh filings being placed in the ebonite cup, the resistance of the circuit will again keep the needle at zero. If now the charged brass sphere is touched with the finger, there is a minute discharge and the galvanometer needle is again deflected. With a few accumulators the experiment can easily be made without a galvanometer. The circuit consists of the battery, some metallic powder, a platinum wire, and a mercury cup. The resistance of the powder is so high that the interuption of the circuit takes place without any sparking at the mercury cup. If now a Leyden jar is discharged in the neighbourhood of the circuit the powder is rendered conducting, the platinum wire immediately becomes red hot, and a violent spark occurs on breaking the circuit.

The influence of the spark decreases as the distance increases, but its influence is observable several metres away from the powder, even with a small Wimshurst machine. Repeating the spark increases the conductivity; in fact, with certain substances successive sparks produce successive jerks, and a gradually increasing and persistant deflection of the galvanometer.

Influence of a Conductor traversed by Condenser Discharges.—While using the Wimshurst machine it was noticed that the reduction in the resistance of the filings frequently took place before discharge. This led me to the following experiment: Take a long brass tube, one end of which is close to the circuit containing the metallic powder; its other end, several metres distant from the circuit, is fairly close to a charged Leyden jar. A spark takes place and the conductor is charged. At the same instant, the conductivity of the metallic powder is greatly increased.

The following arrangement, owing to its efficacy, convenience, and regularity of action was used by me in most of my researches, and I shall briefly call it the A arrangement (see Fig. 1).

The source of electricity is a two-plate Holtz machine driven at from 100 to 400 revolutions. A sensitive substance is introduced into one of the arms of a Wheatstone bridge, or into the circuit of a single Daniell cell at a distance of some 10 metres (34ft.) from the Holtz machine. Between the discharge knobs of the machine and the Wheatstone bridge, and connected to the former, there are two insulated brass tubes, A A′, running parallel to one another 40 centimetres apart. The Leyden jars usually attached to a Holtz machine may be dispensed with, the capacity of the long brass tubes being in some measure equivalent to them. The knobs S were 1mm., ·5mm., or ·1mm. apart. When the plates were rotated sparks rapidly succeeded each other. Experiments showed that these sparks had no direct effect at a distance of 10 metres. The two tubes A A′ are not absolutely necessary, the diminution of resistance is easily produced if only one is employed, and in some cases, indeed, a single conductor is more efficacious. An increase in the speed of the machine increases its action to a marked extent. The sparks at S may be suppressed by drawing the knobs apart, but the conductor A will still continue to exert its influence, especially if there is a spark gap anywhere about.

Effects of Induced Currents.—The passage of induced currents *through* a sensitive substance produces similar effects to those described above. In one instance an induction coil was taken, having two similar wires. The circuit of the secondary wire was closed through a tube containing filings, the galvanometer being also in circuit. Care was taken to ascertain before introducing the filings into the circuit that the currents on make and break gave equal and opposite deflections. Filings were then introduced into the circuit, the primary being made and broken at regular intervals. The following table gives the results obtained in the case of zinc filings:—

ZINC FILINGS.

Galvanometer throws.		Galvanometer throws.	
1st closing	1°	1st opening	18°
2nd „	64°	2nd „	109°
3rd „	146°	3rd „	140°

Effects of Passing Continuous Currents of High E.M.F.—If a continuous current of high E.M.F. is employed, it renders a sensitive substance conducting. The phenomenon may be shown in the following manner. A circuit is made up consisting of a battery, a sensitive substance, and a galvanometer. The E.M.F. of the battery is first one volt, then 100 volts, then one volt. Below I give the galvanometer deflections obtained with an E.M.F. of one volt for three different substances before and after the application of the E.M.F. of 100 volts:

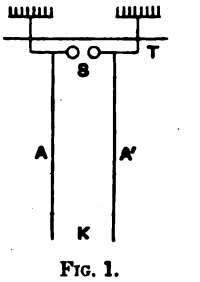

FIG. 1.

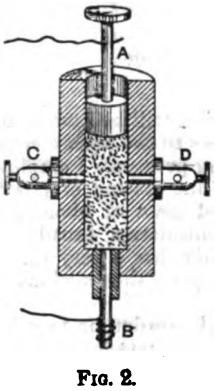

FIG. 2.

Before application of current.	After application of current.
16	100
0	15
1	500

In the case of some measurements taken on a Wheatstone bridge a prism of aluminium filings interposed between two copper electrodes offered a resistance of several million ohms before a high E.M.F. was applied, but only offered a resistance of 350 ohms after the application of this pressure for one minute. The time during which the powder should be interposed in the battery circuit should not be too short. Thus, in one instance the application for 10 seconds of 75 mercury sulphate cells produced no effect, but their application for 60 seconds resulted in the resistance being reduced from several megohms to 2,500 ohms.

It should be observed that the phenomenon of suddenly increased conductivity occurs even if the sensitive substance is not in circuit with a battery at the time it is influenced. Thus, the metallic filings, after having been placed in circuit with a Daniell cell, and its high resistance observed, may then be completely insulated and submitted in this condition to the action of a distant spark, or of a charged rod, or of induced currents. If, after this, the filings are replaced in their original circuit the enormous increase in their conductivity is immediately apparent.

The conductivity produced by these various methods takes place throughout the whole mass of the metallic filings, and in every direction, as the following experiment will show. A vertical ebonite cup containing aluminium powder (*see* Fig. 2) is placed between two metal plates A, B, laterally the powder is in contact with two short rods C, D, which pass through the sides of the ebonite cylinder. A and B can be connected to two terminals of one of the arms of the Wheatstone bridge, C and D being free, and

* Abstract of an article in *La Lumière Electrique*, May 16, 1891.

Digitized by Google

vice versâ. Whatever arrangement is adopted, if a battery of 100 cells is joined up for a few seconds with one or the other of the pairs of terminals, the increase in the conductivity is immediately visible in that direction, and is found to exist also in the direction at right angles.

Substances in which Diminution of Resistance has been Observed.—The substances in which the phenomenon of the sudden increase of conductivity is most easily observed are filings of iron, aluminium, copper, brass, antimony, tellurium, cadmium, zinc, bismuth, &c. The size of the grains and their nature are not the only elements to be considered, for grains of lead of the same size, but coming from different quarters, offer at the same temperature great differences in resistance (20,000 to 500,000 ohms). Extremely fine metallic powder, as a rule, offers almost perfect resistance to the passage of a current. But if we take a sufficiently short column and exert a sufficiently great pressure a point is soon reached when the electrical influence will effect a sudden increase in the conductivity. Thus, a layer of copper reduced by hydrogen, which does not become conducting under the influence of the electric spark or

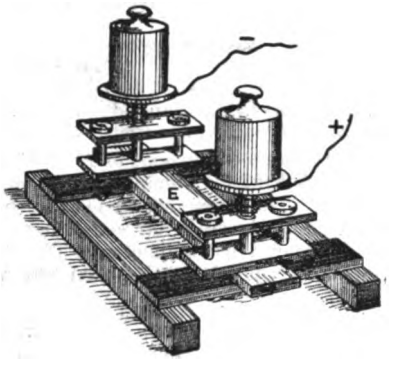

Fig 3.

otherwise, will become so on being submitted to a pressure of 500 grammes to the square centimetre (7lb. per square inch). Instead of using pressure, I employed as a conductor in some experiments a very fine coating of powdered copper spread on a sheet of unpolished glass or ebonite E (Fig. 3), seven centimetres long and two centimetres broad. A layer of this kind, polished with a burnisher, has a very variable resistance. With a little care one can prepare sheets which are more or less sensitive to electrical action.

Metal powder or metal filings are not the only sensitive substances, as powdered galena, which is slightly conducting under pressure, conducts much better after having been submitted to electrical influence. Powdered binoxide of manganese is not very sensitive unless mixed with powdered antimony and compressed.

Making use of the A arrangement with very short sparks at S (Fig. 1), the phenomenon of increased conductivity can be observed with platinised and silvered glass, also with glass covered with gold,

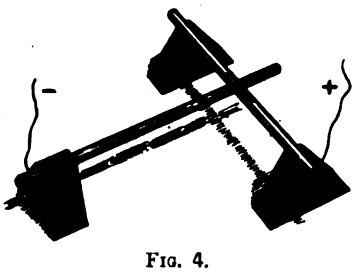

Fig. 4.

silver, and aluminium foil. Some of the mixtures employed had the consistency of paste. These were mixtures of colza oil and iron, or antimony filings, and of ether or petroleum and aluminium, and plumbago, &c. Other mixtures were solid. If we make a mixture of iron filings and Canada balsam, melted in a water bath, and pour the paste into a little ebonite cup, the ends of which are closed by metallic rods, a substance is obtained which solidifies on cooling. The resistance of such a mixture is lowered from several megohms to a few hundred ohms by an electric spark. Similar results are obtained with a solid rod composed of fused flowers of sulphur and iron or aluminium filings, also by a mixture of melted resin and aluminium filings. In the preparation of these solid sensitive mixtures, care must be taken that the insulating substance should only form a small percentage of the whole.

Some interesting results are also obtained with mixtures of sulphur and aluminium, and with resin and aluminium, when in a state of powder. When cold these mixtures as a rule do not conduct either directly or after they have been exposed to electrical influences, but they become conducting on combining pressure with electrical influences. Thus, a mixture of flowers of sulphur and aluminium filings in equal volumes was placed in a glass tube 24mm. in diameter. The weight of the mixture was 20 grammes, and the height of the column 22mm.; with a pressure of 186 grammes per square centimetre (2¼lb. per square inch). The mixture is not conducting, but after exposure to electrical influence, obtained by the A arrangement, the resistance falls to 90 ohms. In a similar manner a mixture of selenium and aluminium, placed in a tube 99mm. long, was not conducting until after it was exposed to the combined influence of pressure and electricity.

The following is one of the group of numerous experiments of a slightly different character. A mixture of flowers of sulphur and fine aluminium filings, containing two of sulphur to one of aluminium, is placed in a cylindrical glass tube 35mm. long. By means of a piston, a pressure of 20 kilogrammes per square centimetre (284lb. per square inch) was applied. It was only necessary to connect the column for 10 seconds to the poles of a 25 cell battery, for the resistance originally infinite to be reduced to 4,000 ohms.

The arrangement shown in Fig. 4 illustrates another order of experiment. Two rods of copper were oxidised in the flame of a Bunsen burner, and were then arranged to lie across each other, as shown, and were connected to the terminals of the arm of a Wheatstone bridge, the high resistance of the circuit being due to the layers of oxide. Amongst the many measurements made, I found, in one case, a resistance of 80,000 ohms, which, after exposure to the influence of the electric spark, was reduced to 7 ohms. Analogous effects are obtained with oxidised steel rods. Another pretty experiment is to place a cylinder of copper, with an oxidised hemispherical head, on a sheet of oxidised copper. Before exposure to the influence of the electric spark, the oxide offers considerable resistance. The experiment can be repeated several times by merely moving the cylinder from one place to another on the oxidised sheet of copper, thus showing that the phenomenon only takes place at the point of contact of the two layers of oxide.

In conclusion, it may be worth noting that, for most of the substances enumerated, an elevation of temperature diminishes the resistance, but the effect of a rise of temperature is transient, and is incomparably less than the effect due to currents of high potential. For a few substances the two effects are opposed.

HIGH-TENSION EXPERIMENTS.

Experiments with currents of excessively high tension are very much *à la mode* just at present, and the following abstract of an account which has appeared in the *Elektrotechnische Rundschau* of some which were publicly carried out last April, in Siemens and Halske's works at Charlottenburg, may prove interesting. The apparatus (see Fig. 1) comprised a 25 H.P. 1,000-volt alternator excited by current from a battery of accumulators. The current from the alternator was taken to a step-up transformer (1,000—20,000 volts), thence along a line to two step-down transformers (20,000—1,000 volts and 1,000—100 volts). The actual existence of the 20,000 volts was rendered visible by the illumination of 200 100-volt incandescent lamps arranged in series across the terminals A B of the first transformer.

According to Herr Kopsel, who conducted the demonstration, the only possible solid insulator for high pressure work is specially prepared vulcanised india-rubber. A sheet of vulcanised india-rubber 1·5mm. thick, and prepared by a special process of Siemens and Halske, was then exposed to a pressure of over 20,000 volts without its being pierced, or, indeed, suffering in any way. Various cables were then exposed to high voltages; one gave at 16,000 volts, and another successfully withstood more than 20,000 volts.

When testing solid insulating bodies, the apparatus shown in Fig. 2 was employed, *m m* being two metal plates in connection with the terminals A B, and J being the substance under test. In order to protect the transformer on the breakdown of the insulation the 200 100-volt lamps were connected in series with the plates *m m*, which arrangement also rendered the rupture of the insulation visible to all present by the incandescing of the lamps. A piece of compressed cardboard 1mm. thick broke down at 2,000 volts, and a sheet of glass of the same thickness gave out when about 10,000 volts were applied. In the case of the latter a beautiful luminous phenomenon was witnessed. A blue glow appeared all round the edge of the brass discs, where they were in contact with the glass, the glow being accompanied by a sharp crackling. When testing liquid insulating bodies the apparatus shown in Fig. 3 was employed. Two brass plates, *m m*, were placed in a glass vessel containing the liquid to be tested, the plates being kept in position by vulcanite distance pieces, *a b c*. The experiments showed that although oil was an excellent insulator it lost this

Digitized by Google

quality in a large measure after it had once been pierced by a spark. *After* the passage of a spark it frequently broke down at 4,000 volts. The reason given was the decomposition of the oil by the spark, and the consequent formation of a sort of conducting bridge of carbon particles.

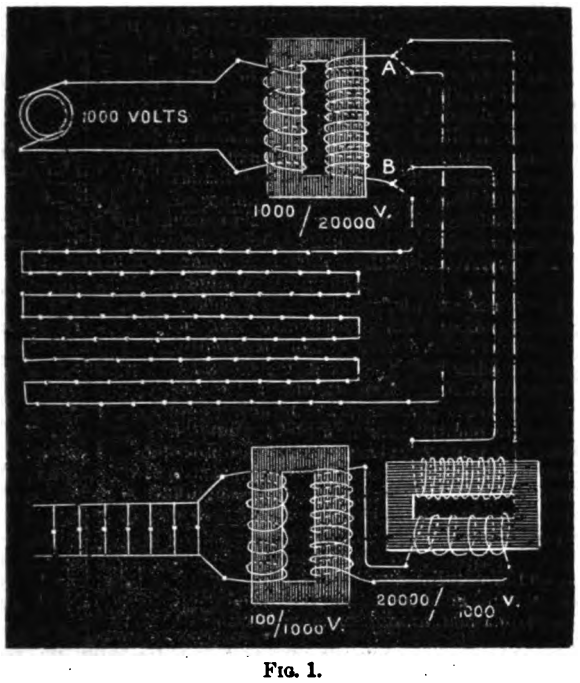

FIG. 1.

Experiments were then made to show the distribution of potential in a transformer. A number of tinfoil electroscopes were connected to a rod of vulcanite, X Y (Fig. 4). On connecting electroscopes to the points A B and C, the leaves at A B diverged, while those at C remained closed; showing that the potential at this

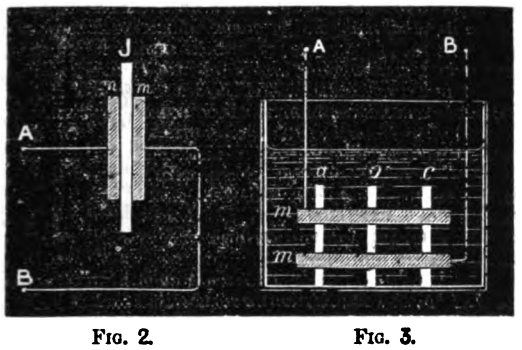

FIG. 2. FIG. 3.

point was the same as that of the earth. If a second transformer was connected up, as shown in the figure, by a wire B*f*, sparks could be drawn from the iron core of this transformer as well as from the secondary coil. Judging by the length of the sparks their potential was equal to the potential of B. The leaves of an electroscope con-

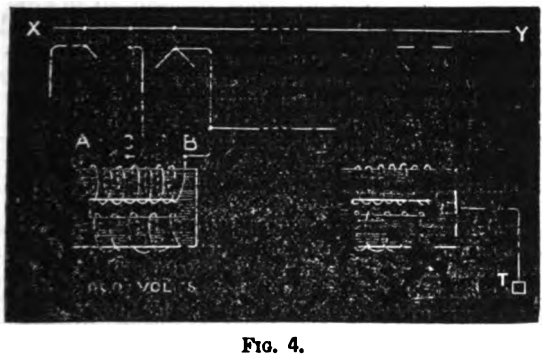

FIG. 4.

nected to the core diverged widely. The distribution of potential was also rendered visible by connecting up the 200 100-volt lamps. While carrying out this experiment, it was observed that the carbon filaments of the lamps nearest the ends of the series vibrated so energetically that at times they struck the bulbs. This phenomenon may be attributed to electrostatic action between the filaments and the glass, and the effect was more marked at the terminals because of the greater difference of potential. On connecting up one end only of the lamps to the transformer, and by choosing lamps with the proper degree of exhaustion, the whole series was made to phosphoresce. This phenomenon may be explained if the globes and the filaments have all the same difference of potential between them; equilibrium would then be produced by a silent discharge. Several experiments on the sparking distances in air of various high pressures were then performed.

THE PRACTICAL ASPECTS OF ELECTRIC WELDING.*

BY FREDERICK A. C. PERRINE, D.SC.

It is hardly necessary to give any description of the general process of electric welding to the Institute of Electrical Engineers. I intend rather to speak of it in actual use, and to discuss some of the problems involved.

The plant with which I have been intimately connected, though not one of the heaviest, is still one making a great number of successful welds in a day, and is one in which the joints are required to be of the highest character, and are subjected to the severest tests. The first machine actually sold by the welding company was bought by the Roeblings, but on account of the delay of the engine builders it was not in place and running for some six months, three or four months after other machines were in satisfactory operation. This was of the direct type, having a double winding on the armature, and the welding done on an apron immediately above the collector terminals of the heavy alternating coils; the pressure was applied by a handle regulated by the workman, the projection also being regulated by a scale stamped on the cam of the handle. Though considered crude, this machine did satisfactory work, often for 24 hours a day, and six days in the week, for about two years, having made about 370,000 splices in telegraph wire during its useful life.

After the automatic machines were brought to a reasonable perfection, we purchased a generator capable of welding up to ½in. copper (40,000 watts), and installed one large transformer, and seven smaller ones of capacity from No. 4 B. and S. copper to No. 18 B and S. These have been at the works something less than one year, and show a daily record of over 1,000 welds in copper and iron wire.

Our attention was drawn to the process at first as a possible solution of a very troublesome problem in preparing and packing iron telegraph wire. For the convenience of the telegraph companies this wire must be put up in bundles, measuring each exactly one-half mile of continuous length. It is very easy to say that the proper weight billets may be bought, and the pieces kept continuous through all the process of manufacture; but, as a fact, these pieces are necessarily irregular in original size, and are often broken in the process of manufacture, and, in consequence, it has long been the custom to make the proper weight bundles by recoiling and splicing with the common telegraph or Lippman's joint, after the wire has been galvanised, jointing before galvanising having proved a failure on account of the acid carried over into the zinc pans by the great helix of the joints.

Singularly enough, the telegraph companies which had for so long accepted as satisfactory these cumbrous connections, immediately commenced to complain of the large burr left by the welding machine, and which we had thought unnecessary to remove. An emery wheel solved this difficulty, however, and we were then able to defy them to find the joint at all. After a very complete series of tests on the joints themselves, the telegraph companies have been finally satisfied, and we are now able to make our bundles of the proper weight and length before the galvanising is put on, and thus save one re-handling of nearly our whole product, besides having removed one of the greatest difficulties and causes of complaint.

"Shorts," as they are technically termed, in copper, are, of course, a still more serious source of loss, not only on account of the greater value of the material, but also on account of the greater liability of this weaker metal to break in the process of drawing, and also on account of the necessarily defective character of a joint in the insulation with which copper wire is usually covered when sent out from the factory. Cables, as you all know, must be made in exact lengths, many of which are often very great, and though a twisted soldered joint might be satisfactory at the bottom of the sea, or covered by a lead sleeve in a manhole, it could not for an instant be tolerated in the body of a cable, which must, before completion of the cable, be passed through exact dies for covering with rubber or lead. Before the introduction of these machines, our custom had been to carefully scarf and fit the joint, which was then brazed with silver solder. While this method makes a strong

* Abstract of a Paper read at the general meeting of the American Institute of Electrical Engineers, New York, May 20, 1891.

Digitized by Google

joint, but little increased in resistance, and thoroughly satisfactory in other respects, it has the disadvantage of being rather slow and difficult to produce, on account of the necessary care in fitting the scarfed ends as well as in soldering and finishing.

Since last November three boys on three machines have made respectively in this work 10,570 welds, 7,642 welds, and 20,421 welds, the registers having been taken on April 16th. Every weld is tested by bending and straining, and if one shows any weakness it is quickly cut out and made again, with the loss only of a very small amount of time and the royalty to the welding company. In all of our welding of sizes below ¼in. the ends are prepared by cutting square across with a pair of pliers, and then setting the cuts at right angles to each other, touching only at the centre, from which the heat radiates to the surface; then, after completion of the weld, the burr is removed by an emery wheel from the iron wire, and by a file from the copper. The preparation and finishing is a little more complex in the larger sizes; the ends are filed to a true butt and chamfered at the edges, and after a reheating in separate clamps the burr of the weld is forged to the diameter of the original rod. The necessity of this will be apparent later on. All of this work is done on either soft steel or copper wire, and is probably of the simplest character done on any machines made by the welding company, consequently the advantages are not so apparent as where the welds are difficult in character on account of complicated shapes.

More varied work is done by the companies of whose plants I now give slight descriptions which may prove interesting. Messrs. Seward and Son, of New Haven, Conn., have at work a machine of somewhat universal character, its employment being principally in uniting Norway iron to Swedish steel, in such shapes as are required in carriage irons and fifth wheels. In this work the burr is removed by a drop hammer at the same heat by which the weld has been made. The crescent tyres of the hundreds of bicycles manufactured by the Pope Manufacturing Company are welded and afterwards formed by dies at the same heat. The material is soft steel. These people also have a machine for brazing their small parts. Besides using the electric welding machine for their telegraph wire, the Trenton Iron Company, of Trenton, N.J., have boldly attempted to make a weld in a wire rope to avoid the tedious, and, with their locked wire rope, impossible operation of splicing. The ordinary joint in a wire rope is from 10 to 20ft. in length, and requires considerable skill on the part of the splicer and his assistants. The operation is to re-twist bunches of wire from opposite strands, and to tuck the loose ends under the adjacent complete strands, which then hold them in place. With the locked wire rope, which is itself but a single strand, the only successful method of joining opposite ends has been to fasten securely around each a cast-iron collar, and, after abutting the ends in a welding machine, to cement the whole together, and afterwards to break off the cast-iron collar, leaving the rope as a solid bar for about 2in. at the weld.

One of the largest and most complete plants at present in operation is that of the Studebaker Bros. Manufacturing Company, of South Bend, Ind. They have at present nine machines; one of them for steel axles up to 1½in. square. After the weld is made it is quickly removed to a drop hammer, making about 300 blows a minute, then at the same heat the axle is set ready for the market. The test for these axles is to bend to 90deg. while hot, and then back to alignment. No instance has yet been reported of an axle breaking under this test, which is frequently made to insure perfect workmanship. They have two machines for welding large car tyres, about 4in. wide and ¾in. thick, and smaller sizes. The weld is made in the usual way and then quickly removed to a hammer, where, by vertical and side blows, the burr is quickly removed. One hammer will easily take care of two welders in constant operation. They have two machines for the hub bands, which are used on the waggon wheels, and they are able to turn out about 1,200 on each machine; besides these there are two or three machines for smaller miscellaneous work. All of the metal used by them is either iron or low grade steel. After the introduction of their plant, their machines made 360,000 welds in less than six months.

Probably the heaviest work done at present in electric welding is that of the Johnson Rail Company, of Johnstown, Pa, who are not, as stated in the journals, welding long lengths of rails together, since, with their continuous mill, they already roll a rail too long to ship, but they find economy in the process in some details of their smaller manufactures. As to the results in general, they say:—"We would state that over a year ago we put in one welder for general work. The bulk of the work done on this machine was work we had totally failed to do by hand welding, not on account of the difficulty of the weld, but on account of the general unreliability of the result. The result of a year's use of the electric welder was, that we have not known one of the welds made by the method to fail, and we have closed contracts with the welding company for four 40,000 watt machines and two 80,000 watt machines, with the intention of adopting the method extensively in our works."

Agricultural machinery has generally been furnished with iron wheels, consisting of a malleable iron hub, into which the spokes are upset, and of a rim into which they are upset at the opposite end. The electro-welding machine has given us two new wheels, each of which is supposed to be preferable to the one described. In the first, manufactured by the Electric Wheel Company, of Quincy, Ill., the hub is cast of malleable iron, with spokes about 3in. long. To these are welded, by one machine, wrought-iron spokes, and, again, by another machine, these spokes are upset into the rim, which is itself welded into a tyre, the product being a wheel of which the spokes are less liable to rattle loose at the hub. The second method is that of Niles and Spott, La Porte, Ind. The hub in this case is composed of two drop forgings of low grade steel, grooved to receive the spokes; one-half is placed on the base of the welder, and the spokes laid in their grooves, then the other half of the hub is put on and the clamp brought down. The current is then applied and the whole, spokes and hub, welded solidly.

The Rogers Typographic Company, Cleveland, Ohio, are practically welding brass to steel, making as many as 800 welds per day, and thus effecting a great saving in the manufacture of their type-setting and founding machines. The hardest steel at present successfully worked by this process is the welding of band saws by the E. C. Atkins Company, of Indianapolis, Ind.; besides the regular work of making the joint in continuous band-saws, these people have ingeniously adopted this method for replacing broken teeth in finished saws. Formerly, they were compelled to cut down to a smaller size any saws from which one or two teeth had been accidentally broken, thus losing not only the difference in price between the two saws, but also the entire cost of labour in cutting the original saw. At present, when a tooth is broken out, they fit in it a new tooth, which is electrically welded in place, and a drop of oil applied at the completing of the heat restores the temper to a serviceable point. Pipe welding, which we all saw successfully accomplished at the factory last year, is put in practice by several companies.

The Electric Pipe Bending Company is engaged principally in manufacturing long continuous coils for ice machines, blast furnace tuyeres, and radiators. With this machinery they not only weld extra heavy black pipe, but also electrically heat the pipe with a machine 20in. between the clamps for the purpose of bending to desired shapes over pipe formers. With continuous coils of pipe it has been necessary for a smith to weld the whole length, 150 to 200ft., before attempting to bend any portion of it, and then after once the bending operation has commenced, in order to get a uniform spiral, the heat is not altered or the bending operation suspended till the coil is complete. Under the present electrical methods the coils are continuously heated in a fire, and the coiling is continuous while one length of pipe is welded at a time, the operation being to attach the welding machine to the end of the moving pipe, and while the forward portion is undergoing the process of bending to weld on a new length, which will be accomplished in a sufficiently short time not to interfere with the coiling apparatus. In all of this pipe welding the burr is beaten down by means of a pneumatic hammer, which is put in rapid motion by the act of closing it around the pipe, a rapid hammer having proved much more effectual than any press or dies. This is probably on account of the more rapid cooling action of the press, since no forming is attempted before the weld is completed and the current is turned off.

For the Charlestown Navy Yard there is about completed a machine for welding ship chains up to 2in. diameter links. These links are formed in halves and fitted roughly to each other, the welds being made in both sides at once by the same heat, which can be regulated to force either side at the will of the operator. When completed, both welds are forged immediately in a die by the same hammer. By this method only the points to be welded are heated, and, as these are immediately forged, one could expect from the process a nearer approach to the strength of rolled metal than where the whole link is heated in the ordinary fire to a welding temperature. The latest development for Government work is the manufacture of conical shell and shrapnel for the smaller armour-piercing guns. With the modern types of armour a cast shell is not of sufficient strength to resist the shock of impact, and in consequence a chrome-steel point is welded to a tool-steel body, embracing the powder cavity. This latter is but small in comparison with that in the old round shell of revolutionary days, consequently the accurate forging of the interior becomes correspondingly difficult. The electrically welded shells are made entirely of forged point, body and base, which may be finished to approximate dimensions, these requiring after welding a minimum amount of machining. The tests on these shells have resulted in a contract for a large number under a guarantee of the manufacturing company.

For a rod to be subjected to further drawing, rolling, or other like processes of manufacture, the weld is satisfactory, since the subsequent working reinstates the metal to its best condition, but

Digitized by Google

for a wire to be considered a finished product, further manipulation is necessary. In view of this, the later machines for welding heavy copper have been provided with reheating clamps and light rapid hammers, by means of which the burr, after a slight trimming, can be reheated and forged; in special cases a further hammering cold is added. Though this produces a great improvement in the metal, it yet leaves a good deal to be desired where great strength and pliability are required. To produce this, a further upsetting of the metal throughout the whole heated space and a subsequent forging will be necessary. This, up to the present time, has not been provided for, and presents a greater difficulty than is at first apparent, besides furnishing a new proof of the crystalline constitution of copper. On account of this characteristic, as is apparent on attempting upsetting in the welding machine, it offers, at a red heat capable of moving and rearranging the particles, a resistance so high to compression, that three or four times the pressure necessary for welding will not have the slightest effect towards increasing the diameter or upsetting. With bronzes the further difficulty is encountered of red shortness between the molten temperature of the weld and the malleable red temperature. That this should be so necessary and offer so many difficulties may seem strange, since the metal does not apparently exceed the temperature of ordinary annealing, and it must be that either the passage of the current by an extra disturbance helps to rearrange the particles, or else the temperature is greater than we imagine from an observation. The latter explanation seems to me to be the more likely, since our ordinary observations are made on metals heated from an external source, and of which the surface is at the highest temperature. With the weld, however, the source of heat is internal, and the surface is undergoing a continual cooling from the external air.

Welds made in the higher carbon steels are at a similar disadvantage, and must be looked upon with disfavour unless provision for upsetting and forging hot is provided. These disadvantages are especially apparent with steel wires of the highest grade, where the strength of the original material has been more than doubled by tempering and drawing. In such cases it is not ordinarily the loss of tensile strength that is to be feared, but the increased liability to snap under repeated bendings. This is especially important in the case of wire to be twisted into a running rope, such as is used on our cable railroads. From this view, the weld in a whole rope where forging is impossible would be necessarily defective, and though for a standing rope I have no doubt it would be fairly successful, yet for a running rope I believe everything tends to prove it dangerous. It has been suggested as an explanation that these effects are due to the presence of oxygen at the weld, producing suboxide in copper and reducing the carbon in steel. In support of this view the case of the application of oil to the hard saw teeth is cited as supplying the necessary carbon by its decomposition. It is undoubtedly a fact that by the heating of these high grade steels, and subsequent slow cooling, some of the combined carbon is changed to the graphitic form, with a consequent loss of strength, and it seems clear to me that a drop of oil at the right moment serves to restore this, or, in other words, effects a tempering. It is almost useless to attempt an explanation by a complicated chemical decomposition, when the simpler molecular rearrangement is more in accordance with the facts and a more complete explanation.

This brings us to a point where the electric welding throws light upon the actual production and nature of burnt steel. By forcing the heat in welding, no matter if rapidly, this effect can be produced as thoroughly as by the means of a fire; while if the name "burnt" was an accurate description, and the iron and carbon oxidised, a sufficient time would be necessary for its penetration into the centre of a bar of metal. This agrees, and is a further confirmation of the most modern ideas about burnt metal, that it is a molecular rearrangement, and by careful forging and heating the metal can be restored to its original state. In this case oxidation certainly does not take place, though the action may be similar to metamorphism in rocks; steel being at the present day looked upon as a mineral, a matrix of iron including minerals which are generally compounds of iron with carbon, silicon, sulphur, manganese or phosphorus. Under this view there may be internal chemical rearrangement at high temperature. With carbon we know this to be the case, but I take it as settled by electrical heating that the change is not necessarily an oxidation.

The welding of two different materials, such as iron and steel or malleable cast-iron, presents another difficulty and possible danger. When such a weld is broken we find that the pressure in the plastic state has forced the iron over the steel, which has itself been merely slightly melted and cemented to the adjacent particles of the iron. This produces what might be called a reverse riveting, the hot iron having been upset over the steel and enclosing it tightly, in the place of having been upset in a hole as in ordinary riveting. Again, as in all this work, the tensile test is but a poor test of quality, and though a weld may have within 10 or 20 per cent. the tensile strength of one of the original materials, it is a fallacy to say that therefore the weld is within 10 or 20 per cent. of the quality of either of them. Use here again determines the serviceableness of the process.

I am tempted here to carry further the discussion of the special cases offered, but it would only be to apply over again the observation indicated in the foregoing, and which might be finally stated that, although the electric welding process will not practically splice everything from a bar of magnesium to a steamer shaft, yet it enables us to accomplish results otherwise impossible, and, if both the use of the product and the treatment of the materials be sufficiently studied, it may be trusted in its results.

LONDON CHAMBER OF COMMERCE.

MEETING OF THE COMMITTEE OF THE ELECTRICAL TRADE SECTION.

A meeting of the Committee of the Electrical Trade Section of the London Chamber of Commerce was held at three o'clock, on Monday last, at the offices of the Chamber, Botolph House, Eastcheap. Amongst those present were Messrs. R. E. Crompton, C. J. Wharton, R. S. Erskine, H. G. Massingham, George Offor, Moritz Immisch, and Bennett Pell.

After the reading of the minutes of the last meeting, the CHAIRMAN (Mr. C. J. Wharton) said that the Secretary (Mr. Murray) had written a strong letter to the Board of Trade with reference to the telephone clauses in the Electric Lighting Orders, in the terms of the resolution passed at the meeting of the Committee on March 20th. The reply of the Board of Trade was then read, in which it was stated that it had always been their object to draw up Provisional Orders which should satisfy both parties. In consequence of the unsatisfactory nature of this reply the Secretary said that, after some consultation, it was decided to abandon the idea of a deputation to the Board of Trade, and to let the matter drop. The Secretary then read Mr. Thomas Parker's report with reference to the proceedings of the Electrical Standards Committee, in which he stated that amongst other things it was proposed to appoint inspectors in certain towns for the purpose of verifying and stamping electrical standard instruments. It was then stated that a letter had been received from Mr. J. E. H. Gordon, enclosing one from his partner, Mr. Rivington, giving particulars of Prof. Mengarini's Tivoli-Rome electrical transmission of power plans.

It was decided to enter Mr. Parker's report on the minutes.

The CHAIRMAN said that although the experience of his firm was that the Board of Trade overhead wire rules were unnecessarily stringent, and his firm had done all they could to obtain their modification, the Board of Trade had refused to move. Under the circumstances, however, he thought it would be inadvisable to forward, as Mr. Gordon suggested, the particulars of Prof. Mengarini's proposed transmission of high-pressure currents by bare overhead wires until the thing was a *fait accompli*.

The SECRETARY then gave the results of the circulars sent out by him to all members of the section with reference to the proposed Electrical Exhibition at the Crystal Palace. Some ten firms were in favour of participating, most of them, however, upon conditions. Some eight or nine firms did not propose to exhibit, and about the same number would like a postponement. Amongst the firms proposing to exhibit were the Edison-Swan Company, Paterson and Cooper, the Acme Electric Works, Ernest Scott and Mountain, &c. The Brush Company thought that there was no call for an exhibition at present, but were prepared to follow the views of the trade generally. Messrs. Goolden and Co. were in favour of postponement, and did not intend to exhibit this year. Major Flood-Page wrote to the effect that he was of opinion that the Exhibition should be postponed until next year, to admit of its being made really international and thoroughly representative, and that in that case the assistance of the Electrical Trade Section and of the Council of the Institution of Electrical Engineers might well be asked for. He suggested that the Secretary should be requested to write to the Crystal Palace authorities asking them to meet the Committee with a view to coming to an agreement favourable to their mutual interests.

A discussion ensued. One member suggested that Olympia was a more suitable place than the Crystal Palace, and there was a general consensus of opinion in favour of the postponement of the Exhibition until 1892. It was finally decided to adopt the suggestion contained in Major Flood-Page's letter to the Secretary, and to ask the Crystal Palace authorities to meet the Committee.

Mr. R. E. Crompton now entered the room and took the chair.

Mr. MASSINGHAM said that the object of the Taunton Exhibition was simply to popularise the electric light throughout the West of England. It was a purely local affair, promoted by the Taunton,

Digitized by Google

Bath, and Exeter Companies, and the space available was very limited. It seemed to him hardly worth while for the Section to take any notice of it, one way or the other.

The CHAIRMAN thought that, with a view of encouraging the scheme, the Secretary might be instructed to write to the Exhibition promoters to the effect that the Committee was in favour of local exhibitions of the kind and wished it every success. This was agreed to.

The notice on the agenda with reference to the Frankfort Exhibition was then discussed.

The CHAIRMAN said the question before them was whether the Electrical Section of the Chamber should meet at the Frankfort Exhibition in a body, thus securing such benefits in the way of formal receptions, guides, &c., as accrued from such a mode of proceeding. He had written to the executive of the Exhibition on the matter, and had received a favourable reply. Two dates had been proposed for the visit, namely, August 5th to 15th, and September 5th to 15th.

It was agreed to circularise the Section on the subject.

Communications were then read with reference to Patent Law reform and confidential trade reports from Germany, and the proceedings terminated.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF LORDS SELECT COMMITTEE CENTRAL LONDON RAILWAY BILL.

The Bill for constructing an underground electric railway from Shepherd's Bush to Cornhill came before a Committee of the House of Lords on Tuesday, Lord Elgin being Chairman.

The promoters were represented by Mr. Pember, Q.C., Mr. Saunders, Q.C., Mr. Freeman, and Mr. Munro. Petitions against the Bill were lodged by the Marylebone Vestry (represented by Mr. Cripps, Q.C.), by the frontagers, lessees, owners and occupiers (represented by Mr. Rigg and Mr. Lewis Coward), by Mr. Maurice Powell, a leaseholder in possession at 2, Kensington Palace Gardens, who appeared in person; and by the London County Council, though the Council was not represented by counsel.

The proposed stations on the line are to be 13 in number, and situated at Shepherd's Bush, Lansdown-road, Notting Hill Gate, Queen's-road, Westbourne station, Marble Arch, Davies-street, Oxford Circus, Tottenham Court-road, Bloomsbury, Chancery-lane, Newgate-street, and Cornhill.

Mr. PEMBER, Q.C., opening his case on the preamble for the promoters, said he had hoped to have spared the Committee from the trouble of many of the details of the Bill, expecting that what opposition was forthcoming would be confined to clauses; but at the last moment petitions traversing the preamble had been lodged. The Bill had twice passed the House of Commons, though it had once had the misfortune of being thrown out by a Committee of the Lords. The motives for the objection on that occasion had, however, been largely removed since that time. Most of the discussion, however, would be on clauses. The line began at Shepherd's Bush and terminated at Cornhill, the entire length being about six miles. There was a small street improvement scheme at Davies-street station included in the Bill, which would be explained by the engineer. The proposed depth of the line would be 50ft. below the surface, which would at once ensure isolation, do away with vibration, and prevent any possible annoyance to anybody on the route. The route traversed would be Oxford-street, New Oxford-street, Holborn Viaduct, and Cheapside. On the point of the utility of the line Mr. Pember said that it had been found that the Metropolitan Railway and the District Line, by avoiding main thoroughfares had been in error, but that very fact showed that the proposed line would not interfere with either of those lines. During the construction of the proposed line Mr. Pember said that no one would suffer any annoyance or impediment to business; and, secondly, there would be no vibration, or smoke, or noise, in working the line. Further, there would be no disfigurement of the streets by girder bridges, as in an overground line. The method of construction would be the same as that adopted on the City and South London Electric Railway. The electric power would be generated at a fixed station at Shepherd's Bush. The great depth (50ft.) of the tunnel would abolish all chance or danger of subsidence. The tunnel tubes would be inserted, and finally fixed in short lengths, and the tubes themselves would have an inside diameter of 11ft. 6in. Hydraulic lifts woud be provided for conveying passengers up and down at each station. It was expected that a speed of 25 miles an hour would be reached, inclusive of the stoppages, which would make an average of about 25 per cent. greater speed than that made on the Inner Circle Railway. The journey from the Marble Arch to the Bank would occupy about 15 minutes, and the entire journey 25 minutes. It was, Mr. Pember said, impossible for London to have another above-ground railway, and it only remained that the traffic should be met in the manner suggested in the Bill. The capital of the promoting Company was between two and two and a-half millions.

Dealing with the opposing petitions, Mr. MAURICE POWELL objected on the ground of being a leaseholder in possession at 2, Kensington Palace-gardens, Paddington, and that, as the proposed line would traverse his subsoil, it would rob him of that subsoil, and also deprive him of the use and enjoyment of certain springs, now yielding him a water supply.

Mr. PEMBER contended that there would be no such dangers as the petitioner feared, and he thought no arbitrator would award much money damages to Mr. Powell. Referring to the petition against the Bill from the frontagers, owners, lessees, and occupiers, Mr. Pember contended that the real basis of the opposition was that, as the proposed line would remove the foot-passenger traffic, their shop trade would suffer.

Mr. GREATHEAD, C.E., was then called, and examined by Mr. Saunders, Q.C. Witness deposed to considerable experience in railway construction, and of late years he had almost exclusively confined himself to tunnelling for railway purposes. He was engineer and inventor of the system carried out on the City and South London Railway. On the proposed line the greatest gradient would be 1 in 100, as compared with 1 in 30 on the South London line. The Bill had a clause forbidding the tunnel to be nearer than 20 feet below the surface at any point. At the stations the tunnel tubes would be about 21 feet diameter. Each train would have six carriages, and would carry 336 passengers. The total cost of the line, with all general contingencies, would be £2,053,000, and for special contingencies £123,000, for electric plant £600,000, and, adding expenses of promotion, &c., the total would be £3,073,000. The capital cost per mile would be £600,000 per mile.

Sir THOMAS FARRER was examined by consent of the Committee and counsel. He was a resident in Marylebone, and knew the points of opposition raised last year by the Vestry. That Vestry were not satisfied with the scheme, on principle, and Sir Thomas, both as a private individual, a ratepayer, and as a public man on the London County Council, was in thorough accord with the scheme. The construction of the line would greatly relieve the surface traffic of the main thoroughfares, and would, therefore, relieve the ratepayers of much of the capital cost of paving, &c., and also of maintenance and repairs. The proposed railway, unlike other railways, would destroy no rateable property, but would create new rateable property. He deemed the scheme extremely important to inhabitants of London, and that was why he, as a public man, appeared in support of it.

Cross-examined by Mr. Rigg: Witness did not think the railway would affect the trade of shopkeepers on the route, and even if it did it was a selfish interest of the shopkeepers not to be compared with the public good.

Mr. GREATHEAD was then recalled, and his cross-examination by Mr. Rigg continued. Witness admitted that, in constructing the City and South London Railway, damage had been done to some houses to some extent, but it was very little, and the claims for compensation were not at all heavy. Witness estimated the cost of working the line at 9d. per train mile.

Sir BENJAMIN BAKER, C.E., was next examined by Mr. Saunders, Q.C. In respect of the alleged probable damage to buildings by the line, witness cited the underpinning of the houses of Cannon-street, which was done with safety, and therefore no danger could accrue by this line, which was not under houses at all. After slight cross-examination, which had no weight, the witness withdrew.

Sir JOHN FOWLER, C.E., then gave evidence in favour of the line.

Sir JAMES WHITEHEAD, representing the Ward of Cheap, strongly favoured the proposed line, as tending to the commercial benefit of the City traders.

Dr. HOPKINSON, consulting engineer for the new line, tendered evidence on electrical technicalities.

Sir FREDERICK BRAMWELL next gave evidence in favour of the scheme. He testified to the complete safety of the boring, and to the complete absence of vibration consequent on working the line.

In cross-examination, he said the proposed line would not cause as much vibration as the ordinary London traffic.

The Committee adjourned till Wednesday, at 11 a.m.

WEDNESDAY, JUNE 24TH.

Mr. RIGG, in addressing the Committee on behalf of certain lessees, owners and occupiers along the route of the proposed line, submitted that if the Bill passed in its present form any person injured by the user of the line would be shut out from compensation. This was practically the same Bill that was thrown out by a Committee of their Lordships' House last Session. It was said that the Bill of last year was rejected because the Committee were not satisfied that the railway could be worked by electricity. He was not present to dispute that the working of a railway by electricity was practicable, but he maintained that the promoters had to satisfy their Lordships not only that they could work the line but that they could make it pay. He regretted that the promoters had not thought fit to call Mr. Mott, who had had great experience of the cost of working an electrical railway, and could have given their Lordships some valuable evidence.

The CHAIRMAN asked the learned counsel whether he intended to call Mr. Mott.

Mr. RIGG replied in the negative. It was not likely, he said, that Mr. Mott would come and give evidence against his own measure. To pay a dividend of 5 per cent. on the capital of the Company it would be necessary for the Company to carry 26 millions of passengers annually. As the London General Omnibus Company, who had 'buses all over London, only carried 100 million passengers per annum, he did not think it was likely that the Central London Railway Company would carry a quarter of that number of passengers over a single line of railway. He submitted that the promoters had wholly failed to prove that they could work the line at a profit, and, therefore, he asked their Lordships to reject the Bill.

After a consultation, their Lordships announced that they considered the preamble proved.

The Bill will accordingly be reported to the House.

LEGAL INTELLIGENCE.

Crompton and Co. v. Phillips Bros.

In the Queen's Bench Division of the High Court of Justice, on Monday, the case of Crompton and Co. *v.* Phillips came before Mr. Justice Day and a special jury. This was an action brought by Messrs. Crompton and Co., of Mansion House Buildings, electrical engineers, against Messrs. Phillips Bros., manufacturers of wire used for electric lighting purposes, carrying on business at Lea Telegraph Works, Hackney Wick, to recover £3,000 damages for an alleged breach of contract. In June, 1889, the plaintiffs required a large quantity of wire for the purpose of supplying the borough of Chelmsford with the electric light, and they ordered it of the defendants. The plaintiffs alleged that, instead of supplying them with wire of the quality and description known as C quality, braided with vulcanised rubber, of at least 0·12 thickness, in accordance with their contract, the defendants sent them wire of a much inferior quality, which was wholly useless for the purpose for which they (plaintiffs) purchased it. The defendants admitted that the thickness of the rubber was not ·12, and that they knew it was to be used by the plaintiffs at Chelmsford, but they denied that it was supplied under the contract set up by the plaintiffs, or that it was unfit for the purposes for which it was supplied. They counterclaimed for £1,405. 18s., the balance due in respect of the wire supplied.

Mr. Moulton, Q.C., and Mr. Graham appeared for the plaintiffs, while Mr. Finlay, Q.C., and Mr. Wallace represented the defendants.

Mr. CROMPTON said that in 1888 his firm undertook to supply the borough of Chelmsford with the electric light, and for that purpose they required a large quantity of insulated wire. His firm wrote to the defendants, asking the prices of their B and C quality, and they replied giving the price of C quality as follows:—No. 10, 23s. 4d.; No. 11, 21s. 3d.; No. 12, 19s. 6d.; and No. 14, 15s. 2d. His firm had purchased large quantities of B quality wire of the defendants, but they resolved to order the C quality for Chelmsford. The defendants supplied his firm with large quantities of the C quality, and about September some of it had been installed at Chelmsford. They tested the work completed, and it worked very badly indeed. At first he was indisposed to find fault with the wire, as he thought that the fault lay in the joints which his firm had made. Having found that an alteration of the joints did not improve matters, his firm tested some of the wire which was not in use, and then discovered the real fault. An inspector of the Board of Trade visited Chelmsford about this time, and his firm had to report to him that the insulation resistance of the whole of the overhead wires was not up to the standard in wet weather, though it was in dry weather. Subsequently they informed the defendants that the wires supplied was not what they had contracted for, and the defendants sent a representative to their works, who admitted that the tests showed that the wire was bad, and asked what they could expect when they purchased very cheap wire. Witness at once denied that they had purchased very cheap wire, and asserted that his firm had paid the highest price that had ever been paid for wire of the kind. The defendants' representative then said the wire was not of C quality, but was a special quality made for the plaintiff company. The insulation was absolutely rotten; he could tear the india-rubber off in short lengths. Good india-rubber vulcanised would last for 20 or 30 years. The price paid by his firm was sufficient to secure a first-rate article. When the suspicions of his firm as to the wire were confirmed they called in an independent expert to test the wire at their own works.

His LORDSHIP (to Mr. Wallace): You deny that it was of inferior quality.

Mr. WALLACE: It was good wire, and useful for a great many purposes. It was not, however, the wire which should have been used for the purpose for which the plaintiffs used it.

His LORDSHIP: You admit that the wire is of inferior quality in a certain sense—not the wire to stand the charge of electricity put into it.

Mr. WALLACE: We do not say it is inferior C quality wire; on the contrary, we say it is the best of that quality.

His LORDSHIP: Then the question for the jury is, whether the wire supplied to the defendants is what is known in the trade as C quality.

Mr. MOULTON: The plaintiffs' case is that it is rubbish, and fit for no purpose. It is not merchantable wire at all.

His LORDSHIP: The defendants must show that the wire is merchantable C wire, and that it is reasonably fit for lighting a town.

Mr. WALLACE: Mr. Crompton says it answered very well in the dry, but not in the wet.

His LORDSHIP: In our climate you must expect occasionally to have a wet day. The question for the jury is whether the wire is a merchantable wire for general purposes.

Mr. WALLACE: For such purposes as C quality is generally employed.

WITNESS, continuing, said the price paid by his firm was ample to enable the best quality of india-rubber to be used. In consequence of the condition of the wire supplied his firm called in Mr. H. R. Kempe, and sent samples to Mr. Hatton. Wire having the defects pointed out in Mr. Hatton's report was useless for electric lighting purposes. The defendants had supplied his firm with about 62,000 yards of C quality wire, and of that quantity about 54,000 yards had been actually put up. He believed that about 16,000 yards had been taken down again, and that the whole would eventually have to come down.

Cross-examined by Mr. WALLACE: None of the wire ordered was intended for inside work. He saw a sample of wire before he ordered the wire in question, and he believed the sample he saw was thicker in diameter than the piece of wire now produced by the defendants. He complained of the quality of the insulation because it was rotten and useless for any electric lighting purposes. He would swear that the sample now produced by the defendants was not shown to him before he ordered the wire in question. He did not tell the defendants for what purpose the wire was required. His firm's experience of the defendants' B quality was that it was nearly, if not quite, equal to the Chelmsford lighting. His firm had purchased B quality for house wiring. He did not know whether or not the manufacturers guaranteed any specific insulation resistance in the case of the B quality, but he believed that they did in the case of C quality. He had purchased D quality wire in small quantities for crossing docks under water. He did not remember getting a guarantee with D quality any more than he did with C quality. His firm never tested goods on delivery. His firm intended to use 2,000 volts at Chelmsford. They had not used such a high pressure before.

Mr. FINLAY, interposing, said the defendants' case was that they were not told that the wire was wanted for such a high pressure.

WITNESS in further cross-examination, said the attention of his firm was first drawn to the wire when it was found that there was no insulation at all in some wet weather. If they had only required a pressure up to 600 volts, they would have put up bare wire. The wire supplied to his firm was not C quality. In his opinion, C quality wire vulcanised was able to stand certainly test up to 1,000 megohms per mile. The india-rubber used was not good. His firm asked Prof. Jamieson, Mr. Kempe, and Mr. Hatton to test the wire.

Prof. ANDREW JAMIESON stated that he went to Messrs. Henley's works, where the samples of the wire supplied to the plaintiffs were being tested. The insulation of the wire was very bad. Mr. Hatton obtained 510 megohms per mile. In his opinion, the wire was not reasonably fit for the purpose of lighting the town with electricity. Four years ago he received from the defendants a case containing wire of different qualities, all properly marked. The wire supplied to the plaintiffs was not similar to the samples he had in his possession. The samples of C quality supplied him four years ago by the defendants were samples of a wire suitable for lighting towns with electricity. He produced his own samples of the defendants' C quality wire, as well as samples of the wire supplied by the defendants to the plaintiffs. The witness here explained to the jury the difference in the two wires.

Cross-examined by Mr. FINLAY: The india-rubber on the wire was so weak that if you pulled it it broke, and there was very little elasticity in it. In properly made C quality wire, he should expect 1,000 megohms per mile. He had not known C quality wire to be used for outside work such as that at Chelmsford.

The further hearing of the case was adjourned till Tuesday.

TUESDAY, JUNE 23RD.

Mr. H. R. KEMPE stated that he had had 18 years' experience in testing and examining insulated wires. In January, 1890, he was called in by the plaintiffs to test some wire. He tested two or three drums of wire which, apparently, had not been touched since they left the manufacturer's factory. The proper way of testing insulation was to put the wire in water, and see what the resistance was. No test would be of any value unless made in that way. In testing the wire he discovered evidences of faulty manufacture. The wire he examined was either not tinned at all, or the tinning had deteriorated. The surface of the wire had turned black. The tinning was for the purpose of preventing the sulphur acting on the copper. If it had been properly tinned the wire would not have turned black. Of the different specimens he examined, one or two showed evident traces of faulty manufacture of the insulation. In some cases the seams had opened, and in others there were cracks every few inches, through which a person could see the conducting wire beneath. It was not properly insulated wire at all. The rubber, in his opinion, was distinctly bad; it had none of the qualities of good rubber. Good rubber would stretch and return again when the extension was taken off. The rubber on the wire he examined would in every case break off short, as if it had no life in it. The wire supplied to the plaintiffs was not equal to the samples of C quality wire produced by Prof. Jamieson. It was perfectly useless as insulated wire.

Cross examined by Mr. FINLAY: He tested the wire by having the drums plunged into a tank of water. He had no recollection of wire of the description supplied to the plaintiffs being employed for outside purposes.

His LORDSHIP: What do you use in the Post Office?

WITNESS: Gutta-percha wire, as a rule—a different class of wire altogether.

In further cross-examination, witness said he had heard of this wire being used for electric lighting purposes, but he could not say it had been used out-of-doors.

Re-examined by Mr. MOULTON: If the rubber had been properly vulcanised the wire could have been used out-of-doors.

Mr. R. J. HATTON, engineer and manager of Mr. Henley's telegraph and electric light cable factory, stated that he was thoroughly acquainted with the proper method of testing cables, and had had a large experience in the business. He tested a number of samples of wire sent to him by Messrs. Crompton. The chief defects he found were cracks in the rubber, and imperfect joining of the seams. He did not know the plaintiffs' C quality wire. He had examined the samples of the defendants' C quality wire, produced by Prof. Jamieson, and found that it was a better quality wire than that supplied to the plaintiffs, because there was a drab rubber next to the wire. He had examined the wire supplied to the plaintiffs electrically, and was of opinion that it was not merchantable.

Cross-examined by Mr. FINLAY: Manufacturers of wire gave a guarantee on the point of insulation. He could get wire from 150 up to 5,000 megohms. He had given his evidence under the impression that a guarantee of 250 megohms was given by the defendants. Vulcanised wire should be tested before it was sent out. The plaintiffs had not got a cheap article. He did not think that his firm had been competing with the defendants.

Re-examined by Mr. GRAHAM: For the purpose of electric lighting he did not call the wire supplied to the plantiffs electric wire at all. It was full of holes.

Digitized by Google

Mr. R. F. HAYWARD, electrical engineer and manager of the plaintiffs' works at Chelmsford, stated that in June, 1889, his firm wanted a large quantity of wire for lighting Chelmsford. Mr. Reed, for the defendants' representative, called at the plaintiffs' works at Chelmsford, and, in the course of a conversation, said that vulcanised wire was the best insulation that could be obtained. Witness told Mr. Reed that his firm intended to have a current of 2,400 volts, and that they had to put the wire on poles in the streets. Mr. Reed told him that vulcanised rubber would be better than pure rubber, and witness ordered C quality wire of the defendants at Mr. Crompton's request. At a subsequent interview with Mr. Reed, that gentleman produced a sample of wire about 6in. or 8in. in length, and witness looked at it but did not take much notice of it. Nothing was said as to the price of the wire on that occasion.

Cross-examined by Mr. FINLAY: He could not recollect whether Mr. Reed showed him the sample as representing the defendants' C quality. He was certain that he told Mr. Reed the wire would be used out of doors, and that the voltage would be 2,400.

Mr. ROOK, storekeeper, in the employ of the plaintiffs, gave corroborative evidence.

Mr. A. H. POTT, electrical engineer at the plaintiffs' works at Chelmsford, stated that the Chelmsford installation was left in his hands. The samples of the wire sent to the works of Mr. Henley fairly represented the bulk supplied by the defendants. He did not think the wire was a merchantable article.

Cross-examined by Mr. FINLAY: There were about 35,000 yards of wire still up at Chelmsford. With the exception of the breakdowns due to the wire the electric light had worked very well at Chelmsford. Portions of the installation gave them trouble each day in wet weather.

This closed the case for the plaintiffs.

Mr. FINLAY, in opening the case for the defendants, argued that before the plaintiffs ordered the C quality wire they knew what they would receive, and that the insulation would not be guaranteed. The defendants never guaranteed the insulation of C quality wire, though they did give a guarantee with their D quality. The wire supplied to the plaintiffs was a fair merchantable article of C quality, but the plaintiffs had not employed it properly. As a matter of fact the plaintiffs had used the wire for a purpose for which it was not intended, and had applied a much stronger current than was usually applied to such wire He maintained that the wire supplied to the plaintiffs was perfectly fit for the use to which C quality wire was universally applied.

Mr. G. R. REED, traveller in the employ of the defendants, stated that he had never seen Mr. Hayward in connection with the wire in question. The wire supplied to the plaintiffs was of C quality, braided. Some time after the wire had been supplied the plaintiffs wired for him to come down to Chelmsford. He went and saw Mr. Crompton, who told him that the wire was useless, and that it did not come up to the insulation resistance the defendants stated. Witness replied that the defendants did not guarantee the resistance, and that he, personally, had not mentioned any specific resistance. It was not the custom of the defendants to guarantee B or C quality wire. The D quality was the only wire the defendants guaranteed. The wire supplied to the plaintiffs was of good quality, and perfectly merchantable. It was the same kind of article as the defendants had been selling for a great many years.

Mr. PHILLIPS stated that he traded as Messrs. Phillips Bros., at the Lea Telegraph Works, Hackney Wick, and that he supplied A, B, C, and D quality of wire for electric purposes. They were all rubber-covered wires, but he did not guarantee any of them, except that known as D quality. He always guaranteed the resistance of his D quality to be 500 megohms. His C quality wire was used indoors for electric lighting. He had never before known of C quality wire being used out-of-doors with a current of 2,000 volts. Nobody would think of using it for 2,000 volts. He certainly should not recommend it to his customers for such a use.

Cross-examined by Mr. GRAHAM: He thought that in a dry place C quality wire was capable of standing 100 volts. He never tested his C quality wire. Some person at his place of business said the resistance of the wire supplied to the plaintiffs was 250 megohms. That was the result of the examination of a short length. The wire tested was immersed in water for a short time only. When he sold C quality wire he intended to sell a good insulated wire for electric lighting. He did not intend it to be full of cracks, though he would not guarantee that there were no cracks in it. He had a good opinion of the C quality wire. It would not be a good article if it were cracked, opened at the seams, and badly joined. He was a manufacturer of wire, but he did not make this particular wire.

Mr. W. H. MASSEY, electric lighting engineer to the Queen's household, stated that the C quality was suitable for indoor wiring of houses. He could not help thinking that the plaintiffs had made a great mistake in using it at Chelmsford. It was never intended to be so used with a current of 2,000 volts. He had compared the wire supplied to the plaintiffs with the samples of C quality produced by Prof. Jamieson, and, so far as he was able to judge, he thought that that supplied to the plaintiffs was the best, because the insulating material was thicker.

Cross-examined by Mr. GRAHAM: The C quality wire which he had used had given perfect satisfaction. He should not be surprised to hear that there were defects such as cracks in the wire supplied to the plaintiffs. If wire containing open cracks were supplied to him he should not put it up, but reject it there and then. The C quality wire was not suitable for out-of-door electric lighting, but it might do where the voltage was low. If, however, the voltage was at all high, he should not use it out of-doors, except in a dry climate.

Mr. W. B. ESSON stated that he had inspected the coils of wire produced by the plaintiffs as specimens of the wire supplied by the defendants for the Chelmsford work. They appeared to be a fair quality of vulcanised rubber. The wire was suitable for indoor use up to 100 volts.

Cross-examined by Mr. GRAHAM: The insulation was not high enough for the wire to be used out-of-doors.

WILLIAM STORR, foreman, in the employ of Messrs. Johnson and Phillips, wire manufacturers, stated that his employers made C quality wire for the defendants. He saw the whole of the wire supplied to the plaintiffs manufactured. It was good, merchantable C quality wire. The copper, tinning, and rubber were all good.

This concluded the evidence for the defendants.

Mr. FINLAY, in summing up the case for the defendants, said the main issue was whether the plaintiffs were entitled to complain that the defendants had supplied them with a wire which had not the insulation they required. He submitted that the defendants had supplied the plaintiffs with the wire they ordered, and that it would be unfair to call upon them to pay damages because the wire would not answer the purposes for which the plaintiffs had thought fit to use it.

Mr. GRAHAM, on behalf of the plaintiffs, maintained that the evidence bore out the plaintiffs' case that the wire was not according to contract, and that it was unfit for the purposes for which it was supplied.

His LORDSHIP, in summing up the whole case, said the witnesses agreed upon the point that it was no good using C quality wire for such a purpose in this country. Had the plaintiffs satisfied them that the defendants had not supplied wire in accordance with the terms of the contract? If they failed they had brought the mischief on themselves, because if by ordering C quality they intended to have a wire to be used out-of-doors, they should have asked for a guarantee as to the insulation.

The jury found a verdict for the plaintiffs, and it was decided that the amount of damages should be assessed by Mr. Kempe and Mr. Massey.

The defendants gave notice of appeal, and execution was stayed.

Lovering v. City of London and Southwark Subway Company.

This was an appeal before the Master of the Rolls, Lord Justice Bowen, and Lord Justice Kay, by the plaintiff from the judgment of Mr. Justice Lawrance. The plaintiff claimed against the defendant Company as mortgagee in possession of Nos. 44 and 45, King William-street, and 6, Arthur-street, in the City, which she alleged had been injuriously affected by cracking and subsidence in consequence of the defendants' use of their statutory powers. Both parties appointed an arbitrator, and the claim was referred to arbitration, and an award of £1,700 was made. The present action was brought on the award, but Mr. Justice Lawrance gave judgment for the defendants, on the ground that, as most of the premises were underlet and the tenants were paying rent to the plaintiff, she was not mortgagee in possession, but only had a reversionary interest in the premises, and that as the under-leases by the plaintiff were not disclosed by the claim, her claim was misleading, and she was not entitled to succeed. The plaintiff appealed.

Mr. Finlay, Q.C., and Mr. A. J. David were for the plaintiff; and Mr. Wheeler, Q.C., and Mr. William Graham for the defendants.

The Court allowed the appeal.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June* 13, 1891.

Patent Litigation.—The present time seems to be a period of especially vicious patent litigation. In addition to the Edison-Westinghouse suit that has just been concluded, and is now awaiting decision, the infringement case between Mr. Brush and the Electric Accumulator Company is up for argument before Judge Cox. It is on this suit more than any other that the rights to the accumulator in this country depend. Last year the suit between the Brush and Julien Companies was decided in favour of the former, but the litigation was not altogether satisfactory, because of arrangements for licences that had been made before the decision was rendered. Several issues of considerable importance were left untouched, and have been taken up in the course of the present suit. Chief among these are the questions relating to the Brush Italian patent, which may serve to invalidate the American one. But this is not all, for the Edison General Electric Company has brought suit virtually against the Thomson-Houston Company, although nominally against the West End Railway Company of Boston, on the fundamental questions of street railway work. The complainant is suing under the Sprague patents that are claimed to cover the field of electric traction. The Thomson-Houston Company owns the Van-Depoele and Bently-Knight patents. As side issues in this suit the rights of Henry, Daft, Field, Adams, and some other pioneers of electric railroad work will be involved. The merits of the case are by no means easy to determine. If the Edison Company should win the suits, we should be treated to a session of litigation with other companies that use virtually the same appliances. As in the invention of the incandescent lamp, a considerable number of men and many patents are involved in this electrical traction issue, and, as in the incandescent lamp suit, too, the suits wi probably turn on the state of

Digitized by Google

the art at the time the patents in litigation were issued. It will probably require several years to reach even a preliminary decision unless the legal proceedings are very much more rapid than they generally are.

Hostility to Electric Traction at Brooklyn.—*Apropos* of electric railroads, the City of Brooklyn is now the scene of a very acrimonious discussion of the trolley system. Several of the street railway companies secured the necessary consents of property owners for the proposed change in motive power, but when the requisite permits from the authorities were applied for it was found that some hostile element had very carefully and thoroughly aroused public sentiment against the road by the customary chain of malicious falsehoods concerning the dangers of overhead wires. Some of the frightened property holders withdrew their consents that had previously been given, and most determined opposition is being made to anything that looks towards electric traction. It is very difficult to understand the real source of this and to find out what interests are so much involved as to induce the necessarily great expense of the litigations that will follow.

Rapid Transit in New York.—In New York the rapid transit situation remains unchanged. The engineers of the Board of Rapid Transit Commissioners are at work drawing up plans that will be presented to the public later; but it is hardly to be expected that anything definite will be announced before the middle of July. The elevated railroad interests are very active in objecting to the underground road, as they have plans of their own that will be seriously interfered with or rendered impossible by any such innovation. They are, however, in such peculiarly bad odour with the public that the favours extended to them will be few and small.

State of the Electrical Industry.—The electrical business in general appears to be flourishing more than is usual for this season of the year. The principal companies all report large orders, and construction work is in active progress all over the country. Among the items of news that are going the rounds at present one may be particularly mentioned; it is expected that within a short time the Edison Company will appear in the field with an alternating current system. This is generally understood to be a concession to the popular demand, for Mr. Edison himself has been persistently and consistently opposed to its introduction. Experiments on the subject have been in progress in the Edison laboratory for a long time, and, besides having Mr. Kennelly at work, the services of Thorburn Reid, an engineer well known in alternating current circles, have been secured. It is hardly probable that any striking innovations in alternating current practice will be attempted, however.

SCANDINAVIAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

COPENHAGEN, *June* 20, 1891.

The Elektriska Aktiebolaget, Stockholm, last year carried out 29 new electric light installations, in addition to which several older ones have been extended. The work done comprises the supply of 22 dynamos, 53 arc lamps, and 4,800 incandescent lamps, besides accumulators. For power transmission, &c., the Company had further supplied 14 dynamos of 227 electric H.P. The Company has, since its formation, supplied 217 dynamos of 2,715 electric H.P., about 22,200 incandescent lamps, and about 90 arc lamps. The Elektriska Aktiebolaget has now amalgamated with the Allmäune Svenska Elektriska Bolaget.

The contract for the municipal central lighting station at Stockholm has been obtained by Siemens and Halske, of Berlin, and the works are to be ready for use by December 1st of the present year. This well-known Berlin firm has to supply two 210 kilowatt dynamos, 280 Tudor accumulators, with an aggregate capacity of 2,500 ampere hours, and all requisite appliances and apparatus; also underground cables for 10,000 simultaneously burning lamps. The dynamos will be coupled direct to their respective engines. Babcock and Wilcox boilers will be used, and the engines are to be supplied by the Lindberg Engineering Works. There are already a good many Siemens and Halske installations in Scandinavia, and this firm has, no doubt, done more work in this country than any other. There is already a fair amount of electric lighting in Stockholm: about a twelvemonth ago there were some 15,000 incandescent lamps and 250 arc lamps.

Both in Christiania and here in Copenhagen the central stations have received considerably more applications for light than had been reckoned upon. In Christiania the first applications amounted to more than 4,000 incandescent lamps, and about 80 arc lamps, although this number was not expected to be reached till the second year. The applicants comprise the Houses of Parliament, the University, the principal hotels, &c. The new Masonic Lodge is the largest consumer, over 600 incandescent lamps and 4 arc lamps. Several applications have also been received for electricity for motive power.

The Stockholm General Telephone Company is indefatigable in its endeavours to accommodate its customers, present and future, and I doubt whether any telephone company boasts a better all-round management than this large concern. The latest move is a telephone for an annual subscription of 10kr. (11s.); for this sum the Company will install a telephone in any house, subject to the user paying 10 öre (1½d.) per telephonic conversation, that is, for any telephonic message the subscriber *sends*; he may *receive* as many as he likes free of any charge. There is an automatic appliance for registering the number of conversations. Separate exchanges will be erected for these 10kr. telephones, and Stockholm will, as far as they are concerned, be divided into 14 districts, each with its exchange; these are to be connected with each other and with the main central exchange. The first of these exchanges will be ready to commence work on October 1st. Stockholm has already the largest number of telephones per hundred inhabitants of any city in the world? What will this percentage grow into when the telephone, by this new arrangement, is brought within the reach of almost everybody?

The Swedish State telephones are also being pushed in all directions with much energy, and Sweden will, ere long, be one complete net of telephones. The last Parliamentary vote was 1,000,000kr., which will be used for extensions in various places, for the purchase of a further number of private telephone companies, &c. In October a grant was made of 600,000kr., which has already been expended some months ago. By the purchases and new installations effected through the means of this latter sum, the number of telephones within the State system was increased from 3,800 to 5,500, an increase representing 45 per cent, resulting in a calculated increase in gross receipts from 364,000kr. to 550,000kr. annually, or about 51 per cent. The 1,000,000kr. are intended for the purchase of the Norrköping, the Nyköping, the Linköping, the Jönköping, the Vexiö, the Örebro, the Köping, and the Söderhaum telephone concerns, which are expected to cost 470,000kr., in addition to which their connection with the State telephone system will entail an outlay of a further 160,000kr. The above telephone companies will bring another 2,000 telephones to the State telephones, and an increase in receipts of 150.000kr. annually, apart from the increase in subscribers, which may safely be calculated upon. There are, however, many applications from different parts of the country, through which, or close to which, the State telephones pass, that they may be brought within the State telephone system, and many of these applications can also be complied with at a comparatively small cost. It is at present under consideration to connect Malmö with Copenhagen by a submarine telephone, some 18 miles long, which would bring Stockholm and Copenhagen in direct telephonic connection. By a telephone from Örebro to Magnor, and from there to Christiania, this latter town will also be in direct telephonic communication with Stockholm.

CORRESPONDENCE.

THE CHEMISTRY OF THE SECONDARY CELL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will you kindly allow me to amend a somewhat misleading remark in the "Retrospect" on the Chemistry of the Secondary Cell, contributed by Mr. Robertson to your issue of June 12th?

In referring to two Papers by Dr. Gladstone and myself, Mr. Robertson rightly says we discovered no ground for supposing that the substance formed by the action of dilute sulphuric acid on litharge or minium respectively to be other than a mixture, and then remarks:—"But as they made use of analysis, their work is open to the objection that they may have destroyed the compound."

I want to point out that this objection cannot apply at all to the method followed in the first of our two Papers—that is,

Digitized by Google

the one dealing with the action of sulphuric acid on litharge. We did not analyse the bodies described by Dr. Frankland. Our method was to add a known excess of acid to a known quantity of litharge, and to study the rate and amount of change each day by determining how much SO_4 had been abstracted from the liquid. This involved no disturbance of the oxysulphate, and yet it told us the composition of the body at any stage of the action.

Curves given in the Paper show the rate of chemical change to a stage much beyond that required by Dr. Frankland's formula.—Yours, &c., W. HIBBERT.

14, Goldhurst-terrace East, South Hampstead, N.W.,
June 22, 1891.

THE NEW PERRY METER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have seen in your last issue the description of Prof. Perry's new meter, and take the earliest opportunity of stating that I consider it in several essential points an infringement of my patents.—Yours, &c.,

Birmingham, June 23, 1891. GEORGE HOOKHAM.

THE WADDELL-ENTZ ACCUMULATOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We were very glad to notice in your issue of May 22nd a description of our Accumulator and Motor.

We regret that, in mentioning the names of the inventors, your correspondent omitted the name of Mr. William A. Phillips, formerly of the firm of Phillips Brothers. Mr. Phillips has been for some years connected with the Edison Company, and is now devoting all his attention to the development of this battery, of which he is one of the inventors. Mr. Phillips is a brother of Mr. Phillips of the firm of Johnson and Phillips.

The results already obtained have been eminently satisfactory, and each day confirms us in our opinion of the practical nature and durability of this battery.—Yours, &c.,

J. A. MACHADO, Sec.

The Waddell-Entz Electric Co., New York, June 16, 1891.

THE ROYAL AGRICULTURAL SOCIETY'S SHOW.

The Royal Agricultural Society of England held their fifty-second annual exhibition during the present week, at Doncaster. There was a very fine display of agricultural machinery and implements, but the only exhibits of interest to our readers are the engines, which have always been a feature at these shows, and which owe a great deal to the elaborate scientific tests which used to be made some ten years ago by the engineers of the Society.

Amongst the leading exhibitors were Messrs. Robey and Co., Messrs. Francis Morton and Co., Messrs. W. H. Willcox and Co., Messrs. W. F. Dennis and Co., the Pulsometer Engineering Company, Mr. E. S. Hindley, the Blackman Ventilating Company, Messrs. Marshall, Sons, and Co., Messrs. Priestman Brothers (Limited), Messrs. Crossley Brothers (Limited), Messrs. Ransomes, Sims, and Jefferies (Limited), and Messrs. Davey, Paxman and Co.

Included in the exhibit of Messrs. ROBEY and Co. were several of their well-known portable, compound, high-speed, vertical, and horizontal fixed engines up to 8 H.P., including a high-speed vertical engine, with 6½in. cylinder and 6in. stroke, suitable for small electric light installations, ship lighting, &c.

The PULSOMETER ENGINEERING COMPANY had on view a large Patent "Deane" Pump, capable of discharging 40,000 gallons of water per hour, and a number of Pulsometer Patent Steam Pumps. There were also on view samples of the Company's various sizes of pumps, and photographs showing many forms of application. This Company's manufactures are well known to many of our readers, and quite a number of Pulsometer and Deane pumps are in use in central stations in this country and abroad. One of the largest size Pulsometers (No. 11½) was on show, suspended as used for well and shaft sinking.

Mr. E. S. HINDLEY exhibited several horizontal and vertical engines, a 3 H.P. hoisting engine, saw benches, donkey pumps, &c. Included in this exhibit was a 4 H.P. vertical engine and boiler on wheels.

Messrs. MARSHALL, SONS, and Co. had a fine exhibit, and amongst the engines shown were a high-pressure horizontal steam engine, fitted with Proell's patent automatic expansion gear; a new horizontal and a vertical engine, both of which are specially adapted for electric light and other machinery requiring steady running. Included in this firm's exhibit are a number of traction engines of Messrs. Marshall's well-known types.

Messrs. PRIESTMAN BROTHERS had on show four different specimens of oil engines (Priestman and Hume's patent): a 2 H.P. horizontal, a 5 H.P. vertical, an 11 H.P. portable, and an 18 H.P. horizontal, the latter fitted with oil cistern, vaporiser, air pump, igniting apparatus, and all details required for the preparation of oil vapour.

Messrs. CROSSLEY BROTHERS had on view six of their well-known gas engines, including a newly-designed high speed engine known as the "E" size, specially arranged to run at 250 revolutions and to give 9 H.P. effective on the belt. Messrs. Crossley Brothers guarantee absolute steadiness with this engine driving direct on the dynamo, and claim that it is unnecessary to fit the dynamo with a fly-wheel or disc. The other engines shown in this firm's exhibit range from a ½ H.P. vertical to a 14 H.P. horizontal, and all these engines are fitted up with the latest improvements—the 14 H.P. being capable of indicating 33 H.P.

Messrs. RANSOMES, SIMS, and JEFFERIES had two very fine exhibits, including their celebrated ploughs, lawn mowers, threshing machines, stacking machines, &c. Amongst the engines shown by this firm was a 10 H.P. compound "new type" engine, fitted with patent automatic governor expansion gear, specially suited for driving electric light machinery.

Messrs. DAVEY, PAXMAN and Co. exhibited one of their compound portable engines and a single cylinder portable engine, which were again selected by the Royal Society for carrying out the trials of the threshing machines. The compound engine is of the "Receiver" type, the cranes being at right angles. The two cylinders are made in one casting, and each cylinder is jacketed, the jacket being formed by forcing a truly turned and bored liner into the outer cylinder. The high-pressure cylinder is fitted with Paxman's patent automatic expansion gear, worked direct by Paxman's patent adjustable high-speed governor. The engine is practically independent of the boiler, so that for high pressures the boiler can be relieved from all undue strains. An efficient feed-water heater is provided. The boiler is of the locomotive type, with flush top. The fire-box is made of specially mild ductile steel, which is expressly manufactured for Davey, Paxman and Co. Messrs. Davey, Paxman and Co. inform us that they have for many years used this steel for fire-boxes, and the results have been most satisfactory. In addition, this firm had on show several examples of their horizontal, vertical, portable, and semi-fixed engines, one of which was shown driving a Marsden stone breaker.

Amongst the miscellaneous exhibitors, Messrs. FRANCIS MORTON and Co. had a fine show of their well-known manufactures; Messrs. W. H. WILLCOX and Co. exhibited a large quantity of engineers' stores, &c.; Messrs. W. F. DENNIS and Co. showed a quantity of specially galvanised steel barbed wire, manufactured by Messrs. FELTEN and GUILLEAUME, for whom Messrs. Dennis and Co. are the British agents; and the BLACKMAN VENTILATING COMPANY were to the front with their well-known fans, several of which were in operation, driven by one of Messrs. F. Ashwell and Co.'s steam engines. Included in this exhibit were fans varying from 24in. to 54in. diameter.

We have again to note the almost entire absence of anything electrical at this exhibition of the Royal Agricultural Society.

BOOKS, &c., RECEIVED.

"Patents for Inventions, and how to procure them." By G. G. M. Hardingham. (London: Crosby Lockwood and Son.)

TRADE NOTES AND NOTICES.

[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.]

NOW READY.—"THE ELECTRICIAN" PRIMERS (38 in all), in two volumes. Price per volume 2s. paper covers, 2s. 6d. cloth; post free, 2s. 2d. and 2s. 9d. respectively. Single copies, 3d.; post free, 3½d. Prospectus on application to the Publisher.

TENDERS INVITED.—The Local Board for the District of Carshalton invite tenders for the lighting of their district, which consists of the entire area of the parish of Carshalton, with gas, oil, or other illuminant, for a period of 12 months from July 31, 1891. Tenders, addressed to the Chairman of the Board, must be deposited at the Board offices, High-street, Carshalton, by 12 noon on July 8, 1891.

——— The Cleethorpes-with-Thrunscoe Urban Sanitary Authority want tenders for lighting the streets and highways within their district with gas or by any other means, for one year, from July 23rd next. Tenders are to be sent to the Chairman of the Board by July 1st.

RESULT OF TENDERS.—Messrs. J. H. Holmes and Co., of Newcastle-on-Tyne, have secured the contract for lighting with electricity the Town Hall of Cleckheaton.

SALES BY AUCTION.—We would remind our readers that the sale of the stock, plant, and machinery of the Electrical Engineering Corporation, Limited (in liquidation), takes place Tuesday next and the following days, at the Alliance Engineering Works, at West Drayton, near the West Drayton station on the Great Western line. Included in the sale is a quantity of steel wire rope and cables, arc lamps, shades, carbon, fuses, mica, dynamos of various outputs, sheet fibre, bolts, nuts, nails, screws, and general electrical engineering stores, portable compound and vertical engines, boilers, planing machines, drilling machines, about 250 tons of iron castings, 10 tons of copper wire, saw benches, vices, forges, pumps, a complete foundry plant, designs, shop drawings, and patterns of vertical high-speed engines and modern dynamos, and included in the sale are eight Telpher passenger cars. The whole stock, plant, and machinery will be on view for two days prior to the sale. Catalogues may be obtained of Mr. F. W. Pixley, 24, Moorgate-street, E.C.; of Messrs. Dowson, Ainsley, and Martineau, 28, Bedford-row, W.C.; and of the Auctioneers, Messrs. Hobson, Richards, and Co., of 79, Coleman-street, E.C. A special fast train leaves Paddington station (main line) at 11:5, arriving at West Drayton at 11:35, on the mornings of the sale.

———Messrs. Wheatley Kirk, Price, and Goulty announce in our advertisement columns that the business known as Quintin Matsys Forge, 14, Griffin-street, York-road, Lambeth, will be sold by auction early in July, unless previously disposed of by private treaty.

PLANT FOR SALE.—The Pilsen Electric Company notify in our advertisement columns that they have for sale a large quantity of dynamos and arc lamps, a 40 H.P. undertype compound engine, a 25 H.P. and a 12 H.P. undertype high-pressure double-cylinder engine, and a quantity of shafting, standards, and belting.

THE TAUNTON ELECTRICAL ENGINEERING EXHIBITION.—Mr. H. C. Willson, manager and secretary of this Exhibition, notifies that firms requiring space in the Exhibition must apply at once, as the last day for receiving entries is the 30th instant. The printers of the official catalogue are Messrs. Goodman and Sons, of Taunton, with whom intending advertisers are requested to communicate.

MATHER AND PLATT'S DYNAMO CATALOGUE.—The fourth edition of the catalogue relating to the Edison-Hopkinson dynamos and motors contains a good deal of information as to the efficiencies and durability of the high class electrical machinery built by this firm. Having a very important general engineering business, of which the electrical department is only a branch, Messrs. Mather and Platt have done well in declining to compete with other manufacturers by attempting to build dynamos which give a large output for their weight and price. By providing very heavy fields, and by refraining from overloading any part, they are enabled to point to the highest efficiencies that have yet been recorded.

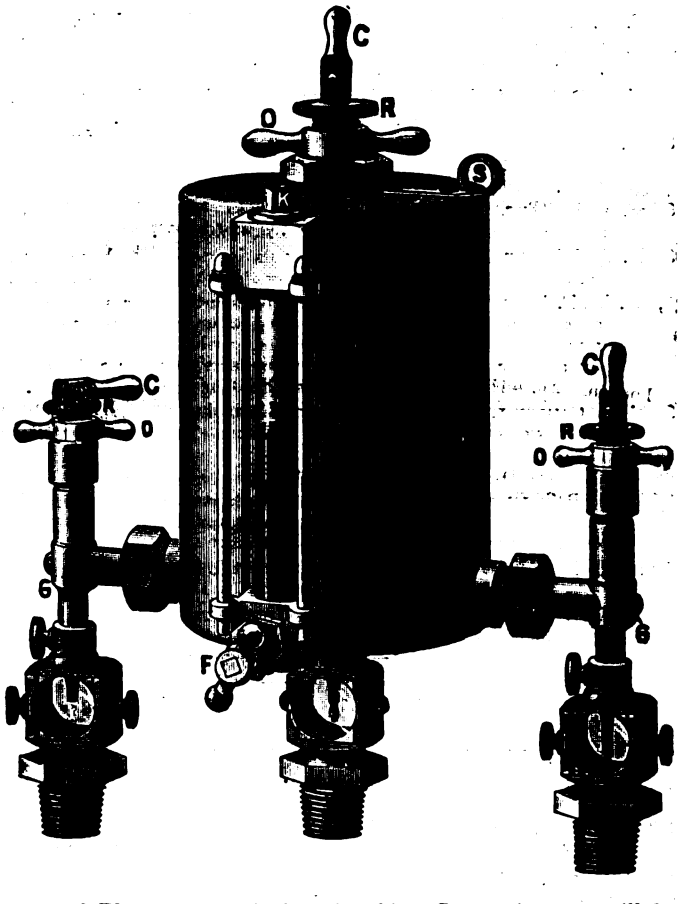
MESSRS. RASHLEIGH PHIPPS AND DAWSON.—At a *conversazione* of the Royal Medical and Chirurgical Society, on the 23rd inst., at which nearly 2,000 of the leading doctors of the United Kingdom were present this firm gave an interesting exhibit of electrical and other appliances, these including:—A small incandescent lamp for examination of mouth and teeth, and looking right down throat; an electro-magnet for removing fragments from the eye; an electric dental drill; an incandescent lamp, with holder for microscope; physicians', practitioners', and patients' batteries; a Cantery battery, with rheostat-canteres and handles; a new form of photophore battery; a lantern worked by 100 c.p. incandescent lamp, throwing many interesting medical subjects on to a large screen; new patent speaking tubes, &c. The rooms were lighted by the electric light installed by the firm, the whole being very effective.

KIRKALDY'S AUXILIARY SURFACE CONDENSERS AND FEED-WATER HEATERS.—We would call the attention of electrical engineers to the display of auxiliary surface condensers and feed-water heaters, made by Messrs. John Kirkaldy (Limited), in the Machinery Hall at the Royal Naval Exhibition. These condensers and feed-water heaters are well worth inspection, as they are both of economic value and of interest to electricians in connection with electric lighting installations.

PROTEAN BATTERY SYNDICATE (LIMITED).—Resolutions were passed at a meeting on May 8th, and confirmed at a meeting on May 29th, that the Syndicate be wound up, and that Mr. John Bidden, 63, Plumpstead-common-road, Woolwich, be the liquidator.

SCIENTIFIC ALLIANCE.—Under the above title, at Nos. 7 and 8, Dyer's-buildings, Holborn, E.C., Mr. H. Dale Vallon has commenced a manufactory for small electric fittings, apparatus for inventors, &c.

POWELL'S TRIPLE SIGHT-FEED LUBRICATOR.—A large lubricator for long dynamo bearings is made by the Wm. Powell Company, of Plum-street, Cincinnati, Ohio. It consists, as will be seen in the illustration, of a reservoir A, holding from one quart to one gallon. It is provided with a gauge glass J. A valve F is provided for cutting off the connection, in case the gauge glass is broken, when a new glass can be fitted by removing the screw K. The three feeders are each provided with a screw collar, R, for adjusting the feed, and this when set to give the desired flow is clamped by the lock nut O. The lubricant can be turned on or off, without affecting the adjustment, by the "signal lever" C. The sight feed is arranged with square glass covers, which may be easily removed for cleaning, and can readily be replaced if broken. This method of separate adjustment and cut off, together with a sight feed, is an excellent one, and for large bearings this triple lubricator should be very useful.



ELECTRIC CONSTRUCTION CORPORATION.—This Corporation informs us that arrangements have been made with the Foreign and Colonial Electrical Power Storage Company, by which their storage battery business at home, as well as abroad, has been transferred to the latter Company. The manufacture of E.P.S. batteries will be continued at the Milwall Works, as heretofore, under the superintendence of Mr. Frank King, who has been so long associated with their development. All orders and correspondence in reference to future business should be addressed to the Secretary, 4, Great Winchester-street, London, E.C.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

May 25, 1891.

8,830. J. A. KINGDON. London. Improvements in the regulation and control of electric currents, particularly applicable to transformers, and in apparatus therefor.

8,845. R. HADDAN. London. Improvements in galvanic batteries. (J. Cabanyes, France).

May 26, 1891.

8,872. J. F. BENNETT and E. P. HIDES. Sheffield. Improvements in galvanic batteries.

8,873. J. F. BENNETT and E. P. HIDES. Sheffield. Improvements in the construction of telephones, electric bells and parts relating thereto.

8,874. J. F. BENNETT and E. P. HIDES. Sheffield. Improvements in telephones and electric bells.

8,876. A. HOSTER. London. Improvements for recording or registering the time during which an electric current is in circuit.

8,892. J. H. ADAMS. London. Improvements in dynamos.

8,896. R. BOLTON. London. Improvements in means or apparatus for regulating or controlling the operation of machinery by electromotive power.

8,922. H. S. PRENTISS. London. Improvements in electric clocks.

8,924. H. H. LAKE. London. Improvements in fuse blocks for electric circuits. (H. S. Haliske, United States).

8,925. C. R. BONNÉ. London. Improvements in electric clocks, watches, or timepieces. (The Société d'Horlogerie, Switzerland).

8,927. W. PAYNE-GALLWEY, W. S. RAWSON, and WOODHOUSE and RAWSON UNITED (LIMITED). London. Improvements in electro-magnetic tools.

8,932. H. H. LAKE. London. Improvements in electric locomotives or street car motors. (R. Eickemeyer, United States).

8,941. A. J. BOULT. London. Improvements in method and apparatus for electrical hardening and tempering. (E. E. Ries, United States).

8,942. W. P. THOMPSON. Liverpool. Improvements in or relating to automatically and electrically stopping railway trains when within a predetermined distance of each other, or when the line is blocked by another train, or it is otherwise dangerous for a train to proceed, and in apparatus therefor. (E. Deming, United States).

8,961. A. CAMPBELL. London. An improved method of measuring electrical currents by expansion of fluid contained in hollow conductors heated by the currents.

May 27 1891

8,963. W. B. SISLING, W. H. SCOTT, and LAURENCE, SCOTT and Co. Norwich. Improvements in the method of wiring for electric lighting and other purposes.

8,991. G. BISHOP. London. An improved electric fire-alarm.

May 28, 1891.

9,029 W. A. TURBAYNE. Manchester. Improvements in electric arc lamps.

COMPANIES' MEETINGS & REPORTS.

House to House Electric Supply Company (Limited).

The third ordinary general meeting of the Company was held last Friday, at the Company's Central Station, Richmond-road, Kensington; the Chairman, Mr. Henry Ramié Beeton.

The SECRETARY (Mr. H. St. John Winkworth) having read the notice calling the meeting,

The CHAIRMAN said: Gentlemen, the report that is in the hands of the shareholders, dealing with the accounts relating to the year 189', refers to the progress of the Company up to the date of its issue, which is approximately 12 months later than the report which dealt with the accounts for the period ending December 31, 1889. From the statements contained therein it appears that the Company has made steady progress during the period under review, although that progress has not been quite so rapid as might have been predicted from that previously experienced. This is partly due to the system of mains having been extended less during the 12 months in question. The result, although it is in strict accordance with the anticipations which I ventured to make on the last occasion when I addressed the shareholders, has been somewhat prejudiced by the increased price of coal, which has, I suppose, averaged 20 per cent. more. You will notice from the chart exhibited on the wall that our growth from the commencement has been steady and continuous, but the revenue account of the Company for the year 1890 relates, of course, to an average demand, and it will be seen from the present report that the number of lamps now connected is upwards of 16,000, as against 7,000 twelve months ago! It is fair to assume, therefore, that the returns for the year 1891 will be based upon an average demand for the 12 months from a number of lamps equivalent to that at present connected in our district. We have been able during this period to effect several economies in working; we have closed our City office entirely; we have dispensed with the draftsmen and canvassers at Kensington; we have reduced our establishment expenses; and we have handed over our installation business to a fittings company on advantageous terms. This introduction of economies will result in the diminution of expenditure to the extent of probably about £1,000 a year; but the full benefit of that economy is not apparent in the balance-sheet now before the shareholders. We see our way to further savings in regard to the water supply and improved appliances, but these can only result from a capital expenditure which we have not felt justified up to the present time in incurring, but which we hope shortly to do. This being the case, I think that the anticipation which I ventured upon last year, that we should now be in the enjoyment of a demand which would ensure us a fair dividend, will be substantiated by the result. I look forward with confidence to a prosperous future for the undertaking. I regret that I am not in a position to announce any definite progress with regard to the disposal of our construction asset, but the matter has continued to receive the attention of the Directors, and we hope that the negotiations now in progress are likely to be soon consummated with satisfactory results. With these observations, I beg to move—

"*That the report and accounts for the year ended December 31, 1890, be received and adopted.*"

The MANAGING DIRECTOR (Mr. Robert Hammond) seconded the motion.
